Chapter 1

Introduction

1.1 Purpose

The SPHERE pipeline is a subsystem of the VLT Data Flow System (DFS). It is used in two operational environments, for the ESO Data Flow Operations(DFO), and for the Paranal Science Operations (PSO), in the quick-lookassessment of data, in the generation of master calibration data, in thereduction of scientific exposures, and in the data quality control. Additionally, the SPHERE pipeline recipes are made public to the user community, to allow a more personalised processing of the data from the instrument.

The purpose of this document is to describe a typical SPHERE data reduction sequence with the SPHERE pipeline. This manual is a complete description of the data reduction recipes offered by the SPHERE pipeline, reflecting the status of the SPHERE pipeline as of 29th July 2016 (version 0.19.0).

1.2 Scope of this document

This document describes the data reduction library for the Sphere instrumenton VLT.It is part of the deliverables.

The main purpose of this document is to present and explain the data reductionsoftware (in form of a library) for SPHERE in general and IFS, IRDIS and ZIMPOL in particular. The structure and content of this document follows the guidelines set out the ESO document "Data Flow for VLT/VLTI Instruments Deliverables Specifications" (VLT-SPE-ESO-19000-1618).

The document presented here follows the layout presented in section 4.5.1of the "Data Flow for VLT/VLTI Instruments Deliverables Specifications" closely with the exception of an added introduction (chapter 1 in this document) and an overview (chapter 2).

The present document describes the design of the data reduction software, including detailed descriptions of algorithms and functions and explainshow to reduce SPHERE data with it.

The examples on running individual pipeline recipes in this manual use the esorex command and manually created list of input files. Several interfaces to automatically organise the data, create the list of input files and execute the pipeline recipes in the proper sequence are available, see https://www.eso.org/pipelines for details.

Please note that the use of Gasgano as a GUI for processing data is deprecated. Its use is no longer recommended and the related section in this manual, as well as support for Gasgano as a

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 7/220

data processing GUI application in general will be dropped entirely in a future release.

The instrument and detector calibrations as discussed here assume that thehardware requirements for the various sub-systems and specified in the corresponding documents are met and that there are no unforeseen instrumentsignatures.

Chapter 2

Overview

In collaboration with instrument consortia, the Data Flow Systems Department(DFS) of the Data Management and Operation Division is implementing data reduction pipelines for the most commonly used VLT/VLTI instrument modes. These data reduction pipelines have the following three main purposes:

- Data quality control: pipelines are used to produce the quantitative informationnecessary to monitor instrument performance.
- Master calibration product creation: pipelines are used to produce mastercalibration products (e.g. combined dark frames, super-flats, wavelength dispersion solutions).
- Science product creation: using pipeline-generated master calibration products, science products are produced for the supported instrument modes.

The accuracy of the science products is limited by the quality of the availablemaster calibration products and by the algorithmic implementation of the pipelines themselves. In particular, adopted automatic reduction strategies may not be suitable or optimal for all scientific goals.

Instrument pipelines consist of a set of data processing modules that canbe called from the command line, from the automatic data management toolsavailable on Paranal or from Gasgano.ESO offers two front-end applications for launching pipeline recipes, Gasgano[14] and EsoRex, both included in the pipeline distribution. These applications can also be downloaded separately from http://www.eso.org/gasgano and http://www.eso.org/gasgano and http://www.eso.org/gasgano and http://www.eso.org/gasgano and http://www.eso.org/cpl/esorex.html. An illustrated introduction to Gasgano is provided in the "Quick Start" Section 3.1 of this manual. Workflows for individual data reduction cascades and detailed descriptions of each recipe's inputs, outputs, parameters and operations can be found in Sections 3.2, 3.3, and 3.4.

The SPHERE instrument and the different types of SPHERE raw frames and auxiliarydata are described in Chapter 4.

A detailed mathematical description of operations carried out inside recipesis given in Chapter 5.

In Chapter 6the installation of the SPHERE pipeline recipes is described together with a few solutions to frequent problems.

2.1 The SPHERE Instrument: IFS, IRDIS and ZIMPOL

In addition to this document, there is the SPHERE user manual [RD10] which gives a brief indtroduction to the instrument, as well as a general description of the available observing instruments

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 11/220

and modes, and details about settingup actual observations.

Chapter 3

Pipeline Guide

This section describes the most immediate usage of the SPHERE pipeline recipes. If you are unfamiliar with ESO pipelines and the plugins called recipes, you can find a basic description of how to operate the things in 3.1. An example workflow for a data set supposedly taken in an IRDIS

observing sequence is described in 3.1.4. More detailed information on the workflow for each instrument and individual recipes can be found in ...

3.1 Quick Start

3.1.1 An introduction to Gasgano and EsoRex

Before being able to call pipeline recipes on a set of data, the data must be opportunely classified, and associated with the appropriate calibrations. The Data Classification consists of tasks such as: "What kind of data amI?", e.g., DARK, "to which group do I belong?", e.g., to a particular ObservationBlock or template. Data Association is the process of selecting appropriate calibration datafor the reduction of a set of raw science frames. Typically, a set of frames can be associated if they share a number of properties, such as instrument and detector configuration. As all the required information is stored in the FITS headers, data associationis based on a set of keywords (called "association keywords") and is specific to each type of calibration. The process of data classification and association is known as data organisation. The DO Category is the label assigned to a data type as a result of dataclassification. An instrument pipeline consists of a set of data processing modules that can be called from different host applications, either from the commandline with Esorex, from the automatic data management tools available at Paranal, or from the graphical Gasgano tool. Gasgano is a data management tool that simplifies the data organisation process, offering automatic data classification and making the data association easier (even if automatic association of frames is not yet provided).

Gasgano determines the classification of a file by applying an instrument specific rule, while users must provide this information to the recipes when they are executed manually using Esorex from the command line. In addition, Gasgano allows the user to execute directly the pipeline recipes on a set of selected files.

3.1.2 Using Gasgano

To get familiar with the SPHERE pipeline recipes and their usage, it is advisable to begin with Gasgano, because it provides a complete graphic interface for data browsing, classification and asso-

Title: SPHERE Data Reduction Pipeline Manual REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 13/220

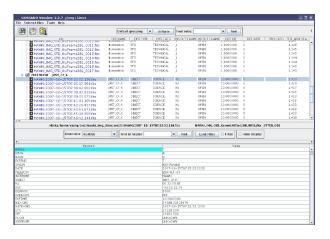

Figure 3.1: The Gasgano main window

ciation, and offersseveral other utilities such as easy access to recipes documentation and preferred data display tools. Gasgano can be started from the Command Line Interface in the following way: gasgano & Figure 4.2.1 shows the Gasgano main window.

With the pull-down-menu File->Add/Remove Files directories containing SPHEREdata can be added. The data are hierarchically organised as preferred by the user. After each file name are shown the classification, the template id, theoriginal file name, the template exposure number and the number of exposures in the template. More information about a single frame can be obtained by clicking on itsname: the corresponding FITS file header will be displayed on the bottompanel, where specific keywords can be opportunely filtered and searched. Images and tables may be easily displayed using the viewers specified in the appropriate Preferences fields.

Frames can be selected from the main window with a <CTRL>-left-click for processing by the appropriate recipe: on Figure 4.2 a set of calibration FITS-files have been selected and after selecting the appropriate recipe, the depicted Gasgano recipe execution window will open, having all the specified files listed in its Input Frames panel. Help about the recipe may be obtained from the Help menu. Before launching the recipe, its parameters may be modified on the Parameter spanel (on top). The window contents might be saved for later use by selecting the Save Current Settings entry from the File menu, as shown in figure. At this point the recipe can be launched by pressing the Execute button. Messages from the running recipe will appear on the Log Messages panelat bottom, and in case of successful completion the products will be listed on the Output Frames panel, where they can be easily viewed and located back on the Gasgano main window. Please refer to the Gasgano User's Manual [RD9] for a more complete description of the Gasgano interface.

3.1.3 Using EsoRex

EsoRex is a command line utility for running pipeline recipes.It may be embedded by users into data reduction scripts for the automation processing tasks.On the other side, EsoRex doesn't offer all the facilities available withGasgano, and the user must classify and associate the data using the information contained in the FITS header keywords (see Section 6).The user should also take care of defining the input set-of-frames and the appropriate configuration parameters for each recipe run: The set-of-frames: Each pipeline recipe is run on a set of input FITS data files.When using EsoRex the file names must be listed together with their DOcategory in an ASCII file, the set-of-frames (SOF), that is required when launching a recipe. Here is an example of SOF, valid for the sph ird instrument flat recipe:

Title: SPHERE Data Reduction Pipeline Manual REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 14/220

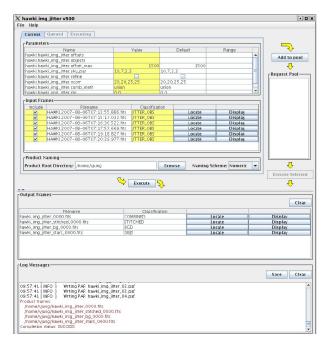

Figure 3.2: The Gasgano recipe execution window

```
\label{eq:calib_master_dark.fits} $$ IRD_MASTER_DARK$ \\ / data/2011-03-27/raw_flat_bright_DIT_0.fits $$ IRD_FLAT_FIELD_RAW$ \\ / data/2011-03-27/raw_flat_bright_DIT_1.fits $$ IRD_FLAT_FIELD_RAW$ \\ / data/2011-03-27/raw_flat_bright_DIT_2.fits $$ IRD_FLAT_FIELD_RAW$ \\ / data/2011-03-27/raw_flat_bright_DIT_2011-03-27/raw_flat_bright_DIT_2011-03-27/raw_flat_bright_DIT_2011-03-27/raw_flat_bright_DIT_2011-03-27/raw_flat_bright_DIT_2011-0
```

Note that the SPHERE pipeline recipes do not verify the correctness of the DO category specified by the user in the SOF. The reason of this lack of control is that SPHERE recipes are just one component of the complete pipeline running on Paranal, where the task of data classification and association is carried out by separate applications. Using Gasgano as an interface to the pipeline recipes will however ensurea correct classification of all the data frames, assigning the appropriate DO category to each one of them (see section 4.2.1). A recipe handling an incorrect SOF may stop or display unclear error messages at best. In the worst cases, the recipe would apparently run without any problem, producing results that may look reasonable, but are actually flawed.

EsoRex syntax:

```
The basic syntax to use ESOREX is the following:
```

```
esorex [esorex_options] recipe_name [recipe_options] set_of_frames
```

To get more information on how to customise ESOREX (see also [13]) runthe command:

```
esorex —help
```

To generate a configuration file esorex.rc in the directory \$HOME/.esorexrun the command:

```
esorex —create-config
```

A list of all available recipes, each with a one-line description, canbe obtained using the command:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 15/220

esorex —recipes

All recipe parameters (aliases) and their default values can be displayed by the command esorex —params recipe name

To get a brief description of each parameter meaning execute the command:

esorex —help recipe name

To get more details about the given recipe give the command at the shellprompt:

esorex — man-page recipe name

3.1.3.1 Recipe configuration:

Each pipeline recipe may be assigned an EsoRex configuration file, containing the default values of the parameters related to that recipe. The configuration files are normally generated in the directory \$HOME/.esorex, and have the same name as the recipe to which they are related, with the file name extension .rc. For instance, the recipe sph_ifs_master_dark has its EsoRex generated configuration file named sph_ifs_master_dark.rc, and is generated with the command:

```
esorex -create-config sph ifs master dark
```

The definition of one parameter of a recipe may look like this:

```
# --ifs.master_dark.clean_mean.reject_high
# Reject high.
ifs.master_dark.clean_mean.reject_high=2
```

In this example, the parameter ifs.master_dark.clean_mean.reject_high (controllingthe number of outliers at the high end to discard when combining frames) is set to the value 2.In the configuration file generated by EsoRex, one or more comment linesare added containing information about the possible values of the parameter, and an alias that could be used as a command line option. The recipes provided by the SPHERE pipeline are designed to be usable ina cascade of data reduction steps, each controlled by its own parameters. For this reason and to prevent parameter name clashes we specify as parameter prefix not only the instrument name but also the name of the step theyrefer to. Shorter parameter aliases are made available for use on the command line. The command

```
esorex —create-config recipe name
```

generates a default configuration file recipe_name.rc in the directory \$HOME/.esorex.A recipe configuration file different from the default one can be specified on the command line:

```
esorex — recipe-config=my_alternative_recipe_config
```

Recipe parameters are provided in Section 9.More than one configuration file may be maintained for the same recipebut, in order to be used, a configuration file not located under \$HOME/.esorex,or having a name different from the recipe name, should be explicitly specified when launching a recipe.

3.1.3.2 Recipe execution:

A recipe can be run by specifying its name to EsoRex, together with thename of a set-of frames.For instance, the following command line would be used to run the recipesph_ifs_master_dark for processing the files specified in the set-of-framessph_ifs_master_dark.sof:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 16/220

```
esorex sph ifs master dark sph ifs master dark.sof
```

The recipe parameters can be modified either by editing directly the used configuration file, or by specifying new parameter values on the command line using the command line options defined for this purpose. Such command line options should be inserted after the recipe name and before the SOF name, and they will supersede the system defaults and/or the configuration file settings. For instance, to set the sph_ifs_master_dark reject_high parameter to 4 the following should be typed:

```
esorex \ sph\_ifs\_master\_dark -- ifs.master\_dark.clean\_mean.reject\_high= 4 \\ sph\_ifs\_master\_dark.sof
```

For more information on EsoRex, see [13].

3.1.4 Example IRDIS Reduction

3.1.4.1 Data set

The data set used in this example is the one used to generate the test sequenceIRDIS-01 in RD11.It can be obtained from http://www.mpia.de/SPHERE/sphere-web/IRDIS-01.tar.gz.This countains the raw data files used in the test described in RD11 andoutlined below. There is no subdirectory structure in the tar file, so it is best to create suitable subdirectory from your working directory and unpack the tarfile in there the following examples will assume that this directiry is named "Raw".

3.1.4.2 Creation of the master dark

To create the master dark, the recipe sph_ird_master_dark must be run.In the IRDIS_EXAMPLE_DATA directory create a file called e.g."master_dark.sof"which should look like this:

Now run

```
\begin{array}{lll} & esorex & sph\_ird\_master\_dark & \\ ---ird.master\_dark.clean\_mean.reject\_low=0 & \\ ---ird.master\_dark.clean\_mean.reject\_high=0 & \\ master\_dark.sof \end{array}
```

to execute the recipe. By the way: A call with

```
esorex —man-page sph ird master dark
```

provides you with a help page.

The recipe will run for a less than a minute. It will then output (your mileage may vary):

```
[ INFO ] esorex: Created product master_dark.fits (in place)
[ INFO ] esorex: Created product static_badpixels.fits (in place)
[ INFO ] esorex: 2 products created
[ INFO ] esorex: Recipe operation(s) took
43 seconds to complete.
[ INFO ] esorex: Total size of 3 raw input frames = 729.95 MB
[ INFO ] esorex: => processing rate of 16.96 MB/sec
```

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 17/220

The first of these is the master dark, the second the bad pixels in a separatefile. View it with your favourite FITS viewer and compare with the input filesto verify that it is indeed the mean of the inputs. Notice that the master_dark fits file has 3 additional extensions – lookat all of them using e.g. ds9 by calling (1 stands for the first extension):

```
ds9 sph ird master dark.fits[1]
```

Later in this manual you can find a description of the recipe in detailand what is stored in the other extensions.

3.1.4.3 Creating the master flat

Similarly to the creation of the master_dark, now create a file called master_flat.sof with the content:

```
\label{eq:raw/sphere_irdiff} Raw/SPHERE\_IRDIFS\_FLAT\_IRDIS210\_0004. \ fits \\ Raw/SPHERE\_IRDIFS\_FLAT\_IRDIS210\_0005. \ fits \\ Raw/SPHERE\_IRDIFS\_FLAT\_IRDIS210\_0006. \ fits \\ Raw/SPHERE\_IRDIFS\_FLAT\_IRDIS210\_0007. \ fits \\ Raw/SPHERE\_IRDIFS\_FLAT\_IRDIS210\_0008. \ fits \\ Raw/SPHERE\_IRDIFS\_FLAT\_IRDIFS\_FLAT\_IRDIS210\_0008. \ fits \\ Raw/SPHERE\_IRDIFS\_FLAT\_IRDIS2
```

Run the recipe using

```
esorex sph_ird_instrument_flat master_flat.sof
```

Again note the tresuling file, irdis flat.fits has in total 4 data units/extensions.

You shoul also experiment with using different parameters. For example, rerun the recipe with

```
\begin{array}{lll} esorex & sph\_ird\_instrument\_flat \ \backslash \\ ---ird.instrument\_flat.threshold=0.9 \ \backslash \\ master\_flat.sof \end{array}
```

look at the output irdis_flat.fits and the first (bad pixel) extension irdis_flat.fits[1] to see the difference.

You may also add a line to the .sof file like

```
master dark.fits IRD MASTER DARK
```

to learn about the influeence of supplying a pre-determined dark.

3.1.4.4 Distortion Map

To correct for the instruments dostortion, a specific map is generated from dedicated calibration data. The corresponding recipe is called "sph_ird_distortion_map", and a good "distort.sof" would look like:

```
Raw/SPHERE_IRDIS072_0004. fits
IRD_DISTORTION_MAP_RAW
master_dark. fits
irdis_flat. fits
IRD_MASTER_DARK
IRD_FLAT_FIELD
```

In the test, the call for the recipe was

```
\begin{array}{l} {\rm esorex \ sph\_ird\_distortion\_map} \ \backslash \\ {\rm \_--ird.distortion\_map.threshold} = 2.0 \ \backslash \\ {\rm distort.sof} \end{array}
```

Title: SPHERE Data Reduction Pipeline Manual REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 18/220

You can experiment with the threshold parameter to learn why it is important. Like all other recipes that involve CPL functions that do thresholding and peak finding, this one is quite sensitive to the threshold provided and a look at the data may be required before calling the recipe.

Note that since no reference grid is supplied, the recipe assumes that the data provided is the reference and generates a reference point table. This is done on the left quadrant. On the right quadrant, which contains of course the identical grid of points, distortion is subsequently measured. You should thus see very small values in the extensions 8 and 12 of the resulting file distortion _map.fits, denoting the distortion in x and y at each pixel.

3.1.4.5 Star center table creation

Now before actually doing the science reduction it is currently necessary to run a prototype version of the sph_ird_star_center recipe. This recipe is responsible to create a table of field centers, which are crucial for any science reduction with IRDIS.To create this table, first create star_center.sof as

```
Raw/SPHERE_IRDIFS_OBJECT_IRDIS210_0034. fits
waffle_lowmaskIRD_STATIC_BADPIXELMAP. fits
master_dark. fits
irdis_flat. fits

and then run
esorex_sph_ird_star_center \
--ird.star_center.sigma=1000 \
--ird.star_center.coll_alg=1 \
--ird.star_center.nsources=4 \
star_center.sof
```

which will create a product called star_center.fits that contains a fitstable carrying the center coordinates found, a time stamp, and the DMS(Detector Motion Staqge) position during the exposure.Not that as again peak finding and thresholding is involved, the corresponding parameters passed to the recipe are quite sensitive, and experimenting always welcome!

Note also that the waffle_lowmaskIRD_STATIC_BADPIXELMAP.fits file is not actually raw data,but simply a mask provided along with the pipeline! You are free to adapt this mask to improve results...

3.1.4.6 Reducing the science data

As the last step the science data is reduced. There are several different recipes available for IRDIS for this step, depending on the mode and the desired algorithm. The standard recipe is the DBI recipe, sph_ird_science_dbi. To run this, create a new science_dbi.sof file which has to be identical to the star center. sof except for the raw file tag names:

```
Raw/SPHERE IRDIFS OBJECT IRDIS210 0038. fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE_IRDIFS OBJECT IRDIS210 0039. fits
                                                      IRD SCIENCE DBI RAW
{\tt Raw/SPHERE\_IRDIFS\_OBJECT\_IRDIS210\_0040.\;fits}
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0041. fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0042. fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0043. fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0044. fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0045. fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE\_IRDIFS\_OBJECT\_IRDIS210\_0046\:.\:fits
                                                      IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0047. fits
                                                      IRD SCIENCE DBI RAW
```

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 19/220

```
Raw/SPHERE IRDIFS OBJECT IRDIS210 0048. fits
                                                       IRD SCIENCE DBI RAW
Raw/SPHERE IRDIFS OBJECT IRDIS210 0049. fits
                                                       IRD SCIENCE DBI RAW
Raw/SPHERE\_IRDIFS\_OBJECT\_IRDIS210\_0050\:.\:fits
                                                       IRD SCIENCE DBI RAW
Raw/SPHERE\_IRDIFS\_OBJECT\_IRDIS210\_0051\:.\:fits
                                                       IRD SCIENCE DBI RAW
Raw/SPHERE\_IRDIFS\_OBJECT\_IRDIS210\_0052\:.\:fits
                                                       IRD SCIENCE DBI RAW
Raw/SPHERE\_IRDIFS\_OBJECT\_IRDIS210\_0053.~fits
                                                       IRD SCIENCE DBI RAW
master\_dark.fits
                                                       IRD MASTER DARK
                                                       IRD FLAT FIELD
irdis_flat.fits
                                                       IRD DISTORTION MAP
distortion_map.fits
star center.fits
                                                       IRD STAR CENTER
```

Note that here not all the science frames in the science_science directoryare included. This is simply to make sure you dont have to wait for several hours for all the data to be reduced!

```
esorex sph ird science dbi science dbi.sof
```

and the recipe writes as main product a file called science_dbi.fits.Congratulations, youre first IRDIS science reductaion has been achieved.Now you can play around with the pipeline to extend your experience andlearn about the options you have.The quality of the test data provided is not outstanding, but you can e.g.try to add the option "-ird.science_dbi.use_sdi=TRUE" to the esorex command line (after the recipe name, as usual!) to get a spectral difference image betweenthe two channels...

3.2 IRDIS

IRDIS offers the following basic observing modes:

- Dual-Band Imaging (DBI)
- Classical Imaging (CI)
- Long-Slit Spectroscopy (LSS)
- Dual-Band Polarimetry (DPI)

The calibration cascade consists of a number of basic calibrations which apply to all modes. The recipes for these basic calibrations are presented in .Mode specific calibration recipes are presented in the subsequent subsections. Each recipe description lists the recipe inputs, both raw frames and calibration products. Also given is a description of the recipe's parameters, and of the output product. From these descriptions it should be possible to construct a workflow. A summary is additionally given in .

3.2.1 Basic IRDIS Calibrations

3.2.1.1 sph ird gain

3.2.1.1.1 Purpose:

Measure the detector gain

		within data cubes		
ird.gain.vacca	bool	Choose the special noise calculation by	0	-
		Vacca et al. (2004) that takes the		
		number of fowler samples into account.		

3.2.1.1.5 Description:

The gain recipe calculates the gain for the detector and derives a mask of nonlinear pixels. The input is assumed to be a series of data cubes, each containg a single extension with N>3 planes that each contain a single exposure. The mean count for each input cube should be different either by increasing the intensity of the illumination source or by using different exposure

Page: 21/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

times. Note that in the latter case the recipe only produces the correct output if the detector gain is independent of the read out mode. The gain recipe, as well as the ron recipe, have a special optional preprocessing step, which corrects some possible bias due to readout electronics settings by first subtracting the median of each input cube from each image in the cube. The gain recipe offers algorithms to calculate the gain, one straightforward fitting algorithm and a more complex fitting algorithm that takes the correct number of fowler samples into account. The second algorithm is switched on using the vacca user parameter and is preferable for accurate gain determinations but can currently not be used to calcuate the detector non-linearity. It is therefore recommended to set the user parameter vacca to 1 when an accurate gain measurement is needed but not non-linearity measurement is needed and 0 in all other cases. In particular for pure monitoring purposes to discover trends in the gain the simpler algorithm is sufficient. For both algorithms the general procedure is similar: The recipes calculates the gain by first collapsing all input cubes to create a single mean image and variance image. The collapse algorithm specified (clean mean by default) and algorithm parameters are used for this process. Once a mean and variance image has been determined the median of the mean image and the corresponding variance is taken as one data point. The collection of input cubes then lead to a collection of data points of median and variance, giving measurements of the variance vs. median relation for the detector. This is then fitted using a polynomial of the specified order (usually 1 or 2). The slope of this curve is the inverse of the gain while the offset gives an estimate of the read out noise. Note that the read out noise estimate obtained here may not be accurate. Please use the dedicated ron recipe to obtain a more accurate estimate of the RON. The estimates of gain and ron are written as keywords in the main recipe product FITS file. If the vacca parameter is set, the recipe corrects the fitting coefficients for the different noise properties expected for different fowler samples. For example, for double correlated reads this corrects the ron by a factor of 2. If the vacca parameter is not set. The recipe determines non linear pixels in a second step. This is done by performing the gain fitting procedure above for each individual pixel. The resulting map of the gain is the data in the first extension of the main product FITS file. Note that the pixel-by-pixel gain values are often very noisy and can not be used to obtain precise gain measurements. Many exposures per input cube are needed to perform accurate pixel fitting. If the fitorder specified is larger than 1, the second order (quadratic) coefficient of the individual pixel fits is saved in an additional FITS file. All pixels that have second order quadratic coefficient larger than the threshold parameter are flagged as non-linear and this resulting map of flags is written out as a third FITS file.

3.2.1.1.6 Products:

Name	Туре	Description		
IRD_ GAIN	FITS[Im(4)]	The linear coefficient of the Photon		
		Transfer Curve (PTC) as image. The		
		file contains the gain values in the first		
		extensions. The second extension		
		contains the bad pixels (static input bad		
		pixels), the fourth extension contains		
		the reduced chi-squared values. The		
		third extension is not used and contains		
		a zero image. The header contains the		
		main gain measurement and its rms.		
IRD_ NONLIN	FITS[Im(4)]	This product is only created if fitorder		
		> 1. It is identical to the main product		
		except that it contains the second		
		(quadratic) coefficients of the pixel fits		
		in the first extension.

				vals.
ird.master_ dark.max_	double	The maximum acceptable value. Any	1000.0	-
acceptable		pixels with values above this are marked		
		as bad.		

3.2.1.2.5 Description:

This recipe deals with the creation of the master dark calibration frame. Only raw frames are used in this recipe. The dark is created by combining the input raw frames using the collapse algorithm specified (usually the clean_mean algorithm). After all input frames are combined in this way, the badpixels are determined on the result. First a simple thresholding is applied using the parameters min_accepting and max_accepting. A smoothed version of the image is then subtracted to remove large scale variations. The smoothing scale can be changed with the corresponding user parameter. Then sigma clipping is used with the sigma user parameter. All pixels that are further than the specified sigma value away from the mean are marked as bad in the combined, unsmoothed image.. This resulting master dark frame is then written out, A separate hotpixel map is also written out.

3.2.1.2.6 Products:

Name	Туре	Description	
IRD_ MASTER_	FITS[Im(4)]	The resulting master dark frame. This	
DARK		frame contains 4 different image	
		extensions: the image, badpixels, the	
		weightmap (how many frames contribute	
		to each pixel), and the rms map.	
IRD_ STATIC_	FITS[Im(1)]	An optionally written single extension	
BADPIXELMAP		image of the static badpixels. Note that	
		the content is identical to the second	
		extension in the master dark frame.	

3.2.1.3 sph ird ins bg

3.2.1.3.1 Purpose:

Creation of an instrument background

3.2.1.3.5 Description:

This recipe deals with the creation of the instrument background calibration frame. Only raw frames are used in this recipe. The background is created by combining the input raw frames using the collapse algorithm specified (usually the clean_mean algorithm). Contrary to the master_dark recipe, no badpixel maps are created by this recipe, since thresholding is much more difficult on the background frames. The recommended way to generate a reliable badpixel map is to use the master_dark recipe on suitable dark frames! MASTER_DARK, INS_BG, and SKY_BG frames are all for subtraction from raw input frames, thus they should never be corrected for flat fields or other dark/background frames!

3.2.1.3.6 Products:

Name	Туре	Description	
IRD_ INS_ BG	FITS[Im(4)]	The resulting master dark frame. This	
		frame contains 4 different image	
		extensions: the image, badpixels, the	
		weightmap (how many frames contribute	
		to each pixel), and the rms map.	
IRD_ INS_ BG_ FIT	FITS[Im(4)]	The smoothed frame (2D polynomial fit)	
		of the background. The FITS file	
		contains 4 extensions: the image, the	
		badpixels, the rms error and a	
		weightmap. Left and right frame fits are	
		obtained separately, but inserted into a	
		full frame result!

		should only give a very rough masking.		
		It is much preferable to select the		
		regions for flat determination using the		
		static badpixel input frame.		

3.2.1.5.5 Description:

The instrument flat field recipe for IRDIS is very similar as the detector flat field recipe for IFS, sph_ifs_detector_flat_field. The flat recipe as described here uses input exposures taken with the narraw band or broad band calibration lamps in any of the IRDIS modes. This flat is used in all subsequent recipes that need to remove the pixel to pixel variation in the signal response of the detector and instrument. It is therefore important that input frames are consistently for one particular instrument configuration and that the resulting flat is applied only to data taken with matching instrument configurations. As input the recipe requires a series of flat exposures

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 28/220

with different median count levels. This may either be achieved by varying the lamp intensity (preferred) or more commonly by varying the exposure time. Dark handling in this recipe is special: For best results, the recipe needs a series of raw dark frames with DITs matching those of the raw flat field frames. If raw darks are provided, the recipe will for each raw flat field frame select the raw dark with the closest matching DIT and subtract it. the recipe will not insist on perfectly matching DITs, this is the user's responsibility! If raw darks are unavailable (e.g. in a automated pipeline context), the recipe can also apply standard irdis background frames. Note that in this case a single dark frame will be subtracted from all input frames. Best results can thus be achieved only if all input raw flat fields have the same DIT (matching that of the background, of course) and lamp intensity is varied to achieve variable flux. The order of selecting what actually happens is the following:

- 1. If raw darks are available, all others are ignored.
- 2. Else if an INS BG FIT is available, this one is chosen.
- 3. Else if an INS BG is available, this one is chosen.
- 4. Else if a MASTER DARK is available, this one is chosen.

The recipe will also run without any dark at all! It is thus the user's responsibility to supply adequate background frames to achieve the best possible results! The recipe creates the flats as follows: All raw frames are read in and dark subtracted. The dark subtraction is performed differently than for other recipes, and rather than master darks, the recipe actually uses raw dark or background frames. Since the background varies significantly depending on the chosen detector integration time, a dark with a matching exposure time needs to be subtracted for each flat. If a specific irdis instrument model is provided via an input frame the irdis instrument model is read from that frame, otherwise a default model is used. This model is used to identify the left and right detector windows. In the next step, a mask of the illuminated region is created by combining all input exposures and using a thresholding above the given input threshold value to identify illuminated regions and masking out non-illuminated regions. Any hot pixels known from the master dark or the provided hotpixel mask are also masked out. The flat fielding procedure descibed below (identical to that for the IFS) is then applied to the left and right windows seperately.

- 1. The mean value is determined for the respective window for all exposures.
- 2. For every pixel p = (x, y), a set of $m_i, v_i(x, y)$ data pairs are stored with m_i being the exposure mean value and $v_i(x, y)$ being the pixel value for exposure i.
- 3. The flat field value of pixel p(x, y) is defined as the slope c(x, y) of a linear fit F to the data $m_i, v_i(x, y)$.
- 4. This slope c(x, y) effectively represents the pixel's response to illumination relative to the detector mean response. It is the flat field value and comes naturally out of the procedure being close to 1.
- 5. The fit itself is performed either using a maximum likelyhood method or a robust fitting method which minimizes the sum of the absolute value of the deviations rather than the sum of the squares of the deviations (see e.g. Numerical Recipes for the algorithm). The robust fitting method will yield better results when significant outliers (e.g. due to cosmic rays) can be expected.
- 6. The flat field values are saved as an image as the main product of the recipe.

Aditionally, the recipe may also produce a separate output of all pixels that are identified as non-linear. The criteria for non-linearity are set by the user parameters and can be either pixels that

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

Page: 29/220

have a flat field value outside specified bounds and/or pixels for which the linear fit produces a reduced chi-squared above a given threshold value. Note that non-linearity pixel determination is performed on the entire detector region and not the left and right window seperately. For reliable non-linearity flagging using the reduced chi-squared it is necessary to use many high quality input exposures. Since the badpixel treatment is somewhat complicated, some important points: the badpixels that are stored in the master flat field itself as produced by this recipe (the second extension of the main recipe product) contain all the badpixels at this point in the cascade. Pixels that were marked as bad from the input static badpixel map are also marked as bad here. The optional static badpixel output that is produced contains strictly only those pixel that the flat field recipe itself deemed to be bad. This does not necessarily include all the badpixels from the static badpixel input file.

3.2.1.5.6 Products:

Name	Type	Description
IRD_ FLAT_ FIELD	FITS[Im(4)]	The flat field. This is saved as a FITS
		file with 4 extensions, the flat values,
		the badpixels (hotpixels and non-linear
		pixels), a weight map (number of frames
		that contributed to each pixel), and the
		rms
IRD_ STATIC_	FITS[Im(1)]	Optional output of all the non-linear
BADPIXELMAP		pixels determined. All pixels as
		determined in this recipe using the
		ird.instrument_flat.badpix_ tolerance
		parameters. This map does NOT
		include all the dark frame badpixels – it
		really only includes those badpixels that
		are bad simply due to the flat field
		criteria.

3.2.1.6.5 Description:

This recipe creates a map of the distortion for the instrument. The raw frames are first reduced like standard science frames in field stabilised mode without dithering. The frame combination is simply done using a clean mean, mean or median combination. If given as input, a dark is subtracted and a flat field applied. Dark handling follows the usual strategy, see man page of sph_ird_science_dbi. For this recipe, providing a dark is optional - it will happily look for points also without subtracting anything in advance! The result frame is then analysed to detect point sources given the user detection threshold specified. Depending on whether a point pattern is given as one of the input frames or not, the recipe now either:

- 1. creates a new point pattern (if none was given) from the raw frames or
- 2. measures the distortion map comparing the observed point pattern with the input point pattern provided.

In case that a new distortion map is created, this is done by

- 1. finding all points in the real image
- 2. making a guess of the optical axis. This is assumed to be the coordinates of the point closest to the geometrical centre of the point pattern. The geometrical centre of the point pattern is calculated averaging the positions of all the points belonging to the point pattern. The centre values are measured relative to the extension of the product. In order to obtain the pixel coordinates in the raw frame 1024 has to be added to the right channel x coordinate.
- 3. shifting the input point pattern so that its most central point has the same coordinates as the optical axis. This means that the central points on real and expected point pattern fall exactly on top of each other.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 32/220

4. determining the distance between each observed (detected) point and the closest point in the input table.

- 5. all points that have been found to be further than the max distortion value given as parameter to the recipe are removed.
- 6. The resulting distortion measurements are then used to calculate two 2D-polynomial fits to create a distortion map in both X and Y for all pixels. Each polynomial has its center of origin on the detector center.

The main product of the recipe is a multi-extension file that gives the distortion map for each IRDIS field of view separately. Other recipes use the polynomial fit as stored in the header of extension 0 and 8 to apply the distortion map. The recipe also produces a number of quality control files when requested to do so. The first is an image of the input point pattern, one total one and one each for the left and right FoVs. In addition the recipe uses the distortion map that has been calculated in the main part of the recipe to correct the input processed raw image. This corrected input is written out as a full detector image as well as left and right FoV subimages. To verify the distortion map is correct the recipe also produces residual distortion QC outputs when full QC output is requested. The absolute residual distortion images are named qc residuals left.fits and qc residuals right.fits. While these may show outliers, a high quality distortion measurement should yield residual images with typical values < 0.1. A stronger test of the quality of the distortion map quality can be made by feeding the full detector control image back into a second run of the distortion map recipe. The resulting distortion map then gives the distortion residuals - and these should all be close to 0. The polynomial fit is available as QC parameters in the distortion map. The polynomial fitting is performed on the point patterns shifted by the centre of the optical axis. The fitting generates two polynomials: $p_x(x,y)$ and $p_y(x,y)$ where the first provides the shift in the x direction for a point of coordinates (x,y). $p_y(x,y)$ refers to the shift in the y coordinates. The coefficients of the polynomials are written as QC parameters in the form "ESO DRS DIST L X COEFF i_j" where "L" indicates that the QC parameter belongs to the left FOV (for right FOV "R" is used). The letter "X" indicates that the coefficient belongs to $p_x(x,y)$ ("Y" is used for $p_y(x,y)$). i and j are the powers of x and y, i.e. x^iy^j . The pin point static calibration is shifted to the closest pin-point image. This shift is stored as the estimated optical axis in the keywords "ESO QC DISTMAP OPT AXIS X" and "ESO QC DISTMAP OPT AXIS Y". Then the polynomial fit is applied as described above and saved as DISTORTION MAP, which is used in later steps of the cascade to correct the optical distortion.

3.2.1.7.5 Description:

This recipe creates a table with centre star positions. The input raw frames are each reduced by subtracting the dark and applying the flat provided. Dark handling follows the usual strategy, see man page of sph_ird_science_dbi. For this recipe, providing a dark is optional - it will happily look for points also without subtracting anything in advance! After sorting the frames, the recipe only reduces the image data of the waffle images. An optional mask frame may be given, of the same dimensions as the raw input frames, which allows masking out of regions before the point sources are detected. This can mainly be used on images where despite use of a coronagraph a significant central signal is present. The left and right parts of the illuminated detector regions are extracted and left and right part are separately analysed using a aperture detection algorithm. The aperture detection algorithm detects all connected regions of at least 4 pixels size (area) that are the given sigma above the background. The so detected waffle stars are then used to contruct a geometric centre of all stars found. This is then the frame centre. The recipe also works for the case that there is only one star (e.g. the coronograph is out and no waffle stars are formed). After frame centers have been determined for all waffle images an internal table is created with an entry for each waffle image, giving the time of the start of the exposure and the centre information. The recipe reads the position of the IRDIS DMS from the header of the raw frames, divides by 18.0 to convert from micron to pixels, and stores them in the output table.

3.2.1.7.6 Known Issues:

While this recipe is functional, its requirements are fully settled. The recipe implementes the current baseline of how star centering is foreseen in IRDIS.

3.2.1.7.7 Products:

Name	Туре	Description
IRD_ STAR_	FITS[Table]	The table of stellar center positions as a
CENTER		FITS table, with one row for each input
		raw frame. The order is the same as the
		order of input raw frames.

REF: VLT-TRE-SPH-14690-660/1/0

3.2.2 IRDIS Dual-Band Imaging (DBI) Specific Calibrations and Science

3.2.2.1 sph ird flux calib

3.2.2.1.1 Purpose:

Calibrate the effect of coronagraph

3.2.2.1.2 Input frames:

Data Type (TAG)	Source	Optional	Min	Max

calib.outfilename		Please also see the esorex documentation		
		for naming of output products.		
ird.flux_ calib.coll_ alg	int	The collapse algorithm to use. $0 =$	2	0,1,2
		Mean, $1 = Median$, $2 = Clean mean$.		
ird.flux_ calib.clean_	int	The clean mean reject pixels on high	1	0-20
mean.reject_ high		end.		
ird.flux_ calib.clean_	int	The clean mean reject pixels on low end.	1	0-20
mean.reject_ low				

3.2.2.1.5 Description:

This recipe calibrates the effect of the coronagraph on the detected number of counts. For this purpose the raw frames with and without coronagraph are reduced seperately in the standard way (dark subtraction, flat fielding). The recipe then measures the total flux in the coronagraph and the non-coronograph frames and saves the ratio as a keyword together with the reduced images.

3.2.2.1.6 Products:

Name	Туре	Description
IRD_FLUX_CALIB FITS[Im(4)]		The reduced frame with the calibration
		keywords in header.

3.2.2.2.5 Description:

This recipe creates the reduced science frames for all science observations with IRDIS in DBI maging mode. The recipe supports dithered frame combination, as well as ADI and SDI The frames are reduced in the following steps:

- 1. The input raw frames are dark subtracted, see below
- 2. a flat field is divided out if it is provided
- 3. a badpixel map is created for each frame that contains the union of all dark and flat field badpixels ***(does not work)***
- 4. the left and right IRDIS subframes are extracted using the IRDIS instrument model as specified in the header of the flat field (if provided) or the default model otherwise.

Now, for each of the subframes the processing is as follows:

- 1. high frequency filtering ***(switched off by default)***. If the filter radius f_r is set to a value larger than 0, a top hat frequency filter is applied, masking out all frequencies above the value of $f > f_r \times f_{max}$, where f_{max} is the maximum frequency in the FFT. For noise filterings a value between 0.9 and 0.99 are good values to use for f_r .
- 2. FFT or warp shifting of image to recenter the image
- 3. Application of the distortion map to image
- 4. Shifting and distortion map application to badpixel map using geometrical approach

All these processed frames are then saved as temporary files. These are then combined to create a reference speckle image. Now the ADI or SDI steps are performed if one of them or both are selected. If not is selected, these steps are skipped.

- 1. The speckle frame is subtracted.
- 2. if SDI is selected, scaling of the images using FFT around the image center the angle should be given as part of the field center table provided in the input of the recipe.
- 3. if ADI is selected, rotation of the images using FFT around the image center the angle should be given as part of the field center table provided in the input of the recipe.

If the angles are not specified by the field center table, and ADI is turned on, the images will be aligned by rotating them all to a parallactic angle of zero. Then these frames are combined using the selected combination algorithm.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 39/220

• if a weighted mean is selected, a weightmap is calculated first taking the median frame as a reference frame and weighing down the other frames depending on the difference in values. Note that this is still a very experimental option and it is still to be defined what weighting sheme would be optimal. All badpixels get assigned the weight of 0. Frames are then combined taking the individual weights into account.

- if a mean is selected, frames are combined using a mean, after first rejecting all bad pixels.
- if a median is selected, frames are combined by taking the median pixel value at each pixel position. This procedure ignores the badpixels.

The obtained combined results for the left and right IRDIS field of view are saved in a single FITS file with 8 extensions, following the layout for a double master frame: the first four extensions being the image, badpixelmap, N map, and rms for the left field and the second set of four extensions being the equivalent for the right field. Some additional notes:

- The static badpixel frame is optional and the badpixels defined there will be combined (using a logical OR) with badpixels in the dark or flat.
- Before the images are transformed (rotated and/or shifted) badpixels are interpolated. Interpolation happens irrespective of algorithm choice. The interpolation is a simple 8 neighbour pixel average. In case a number of n < 8 neighbour pixels are also bad, 8 n values are used. In case all neighbour pixels are bad, the interpolation simply copies the value from nearest non bad pixel.
- While a filter table is not strictly required, no scaling will be done if SDI is selected, leading to zero images.
- For a point-source an estimate of the Strehl ratio may be useful. The presence of a filter table frame will enable the estimation, which on failure will do nothing and on success will insert Strehl related QC parameters into each product header.

Dark handling: This recipe will not run without a supplied dark or background frame. Possible frames to be subtracted are SKY_BG_FIT, SKY_BG, INS_BG_FIT, INS_BG, and MASTER_DARK. DIT and readout mode should match the science data, but this is not verified by the recipe! For everything except MASTER_DARK, it is a wise idea to also match the filter configuration! If you provide more than one of the optional frames, a choice will be made according to the following priorization:

- 1. If a SKY BG FIT is available, this one is chosen.
- 2. Else if a SKY BG is available, this one is chosen.
- 3. Else if an INS_BG_FIT is available, this one is chosen.
- 4. Else if an INS_BG is available, this one is chosen.
- 5. Else if a MASTER_DARK is available, this one is chosen.
- 6. Else an error will be thrown and execution terminated.

3.2.3.1.5 Description:

This recipe creates the reduced science frames for all science observations with IRDIS in classical imaging mode. The recipe supports dithered frame combination, but does not currently support any frame de-rotation. Use the ***sph_ird_science_dbi*** recipe for cases when de-rotation is needed. The frames are reduced in the following steps:

- 1. The input raw frames are dark subtracted, see below
- 2. a flat field is divided out if it is provided
- 3. a badpixel map is created for each frame that contains the union of all dark and flat field badpixels ***(does not work)***
- 4. the left and right IRDIS subframes are extracted using the IRDIS instrument model as specified in the header of the flat field (if provided) or the default model otherwise.

Now, for each of the subframes the processing is as follows:

- 1. high frequency filtering ***(switched off by default)***. If the filter radius f_r is set to a value larger than 0, a top hat frequency filter is applied, masking out all frequencies above the value of $f > f_r \times f_{max}$, where f_{max} is the maximum frequency in the FFT. For noise filterings a value between 0.9 and 0.99 are good values to use for f_r .
- 2. FFT shifting of image to recenter the image
- 3. Application of the distortion map to image
- 4. Shifting and distortion map application to badpixel map using geometrical approach

All these processed frames are then saved as temporary files. Then these frames are combined using the selected combination algorithm.

• if a weighted mean is selected, a weightmap is calculated first taking the median frame as a reference frame and weighing down the other frames depending on the difference in

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 43/220

values. Note that this is still a very experimental option and it is still to be defined what weighting sheme would be optimal. All badpixels get assigned the weight of 0. Frames are then combined taking the individual weights into account.

- if a mean is selected, frames are combined using a mean, after first rejecting all bad pixels.
- if a median is selected, frames are combined by taking the median pixel value at each pixel position. This procedure ignores the badpixels.

The obtained combined results for the left and right IRDIS field of view are saved in a single FITS file with 8 extensions, following the layout for a double master frame: the first four extensions being the image, badpixelmap, N map, and rms for the left field and the second set of four extensions being the equivalent for the right field. Some additional notes:

- For a point-source an estimate of the Strehl ratio may be useful. The presence of a filter table frame will enable the estimation, which on failure will do nothing and on success will insert Strehl related QC parameters into each product header.
- If additionally a standard star table is supplied and the target observed can be found in that table, an estimate of the zeropoint is also computed.

Dark handling: This recipe will not run without a supplied dark or background frame. Possible frames to be subtracted are SKY_BG_FIT, SKY_BG, INS_BG_FIT, INS_BG, and MAS-TER_DARK. DIT and readout mode should match the science data, but this is not verified by the recipe! For everything except MASTER_DARK, it is a wise idea to also match the filter configuration! Strehl Ratio Calculation: The recipe calculates the Strehl Ratio following these steps:

- 1. Optionally correct the residual local sky background evaluated in an annular region centered on the expected peak of the Point Spread Function (PSF). The region extendes between bg_r1 and bg_r2. The center is the centroid of the apertures found in the image.
- 2. The PSF is identified and its integrated flux is normalized to 1. The flux is integrated in a circular region having radius star r;
- 3. The PSF barycentre is computed and used to generate the theoretical normalised PSF. It depends on the pixel scale (PIXSCAL extracted from the raw header) and on the nomial filter wavelength extracted from SPH IRD TAG FILTER TABLE CALIB;
- 4. The Strehl Ratio is the ratio between the maximum intensities of the PSF and the theoretical PSF.

Zeropoint Calculation: The recipe calculates the Zeropoint following these steps:

- 1. The zeropoint calculation uses the integrated flux (f) of the star determined as part of the Strehl Ratio computation;
- 2. The standard star magnitude (m) is extracted from SPH_IRD_TAG_PHOT_TABLE_CALIB according to the filter employed;
- 3. The exposure time (t) is extracted from the raw header;
- 4. The zeropoint is calculated as:

$$z = m + 2.5 * \log 10(f/t) \tag{3.1}$$

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

5. The zeropoint z is corrected by a correction factor c extracted from the appropriate extension of SPH IRD TAG FILTER TABLE CALIB:

$$z_c = z - c \tag{3.2}$$

Page: 44/220

6. Both z and z_c are written in the output products as QC parameters, e.g. for the left field we have ESO QC ZPOINT LEFT and ESO QC ZPOINTCORR LEFT respectively;

If you provide more than one of the optional frames, a choice will be made according to the following priorization:

- 1. If a SKY BG FIT is available, this one is chosen.
- 2. Else if a SKY BG is available, this one is chosen.
- 3. Else if an INS BG FIT is available, this one is chosen.
- 4. Else if an INS BG is available, this one is chosen.
- 5. Else if a MASTER DARK is available, this one is chosen.
- 6. Else an error will be thrown and execution terminated.

${\rm mean.reject_\ low}$				
ird.wave_	double	Threshold for line detection. This value	1000.0	-
calib.threshold		is used for line detection to determine a		
		rough estimate of dispersion and the		
		line positions before the more careful		
		wavelength calibration is done. The		
		value here should be between the		
		background and the maximal value of		
		the faintest line visible on the image. If		
		the value is negative (default), the		
		threshold is set to ten times the image		
		mean value.		
$ird.wave_\ calib.smooth$	double	When set to a positive value, the raw	0.0	-
		input data is smoothed with a gauss of		
		the given FWHM before lines are		
		detected and peaks determined.		
ird.wave_	double	The wavelength of first line [nm].	987.72	-
$calib.wavelength_\ line 1$				
ird.wave_	double	The wavelength of second line [nm].	1123.71	-
$calib.wavelength_\ line 2$				
ird.wave_	double	The wavelength of third line [nm].	1309.0	-
calib.wavelength_ line3				
ird.wave_	double	The wavelength of fourth line [nm].	1545.07	-
calib.wavelength_ line4				
ird.wave_	double	The wavelength of fifth line [nm].	1730.23	-
calib.wavelength_ line5				
ird.wave_	double	The wavelength of sixth line [nm].	2015.33	-
calib.wavelength_ line6				
ird.wave_ calib.line_	int	The maximal pixel tolerance around	5	-
tolerance		which lines are searched for peaks in		
		exposure.		
ird.wave	int	The number of lines to use. Any input	6	2-6
calib.number_ lines		wavelength value for lines with a		
_		number higher than the total number of		
		lines to use are ignored.		

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 46/220

Name	Type	Description	Default	Allowed vals.
ird.wave_ calib.degree	int	The polynomial degree to use for the	3	1-6
		fitting. This should always be at most		
		one less than the number of lines used.		
ird.wave_	int	The width of the sliding window used to	200	-
calib.column_ width		average pixels together before the		
		wavelength solution is found.		
ird.wave_ calib.grism_	string	Switch between grism mode (TRUE),	AUTO	-
mode		prism mode (FALSE), or automatic		
		(AUTO). In auto mode, the		
		ESO.INS1.OPTI1.NAME keyword		
		determines the mode, whether grism or		
		prism. In grism mode the fitting		
		coefficients $c2 = c3 = c4 = 0$, and the		
		corresponding user parameters are		
		ignored.		
ird.wave_ calib.c2	double	The c2 coefficient in the fit	-43.352	-
ird.wave_ calib.c3	double	The c3 coefficient in the fit	149.723	-
ird.wave_ calib.c4	double	The c4 coefficient in the fit	82.442	-

3.2.4.1.5 Description:

This recipe performs the wavelength calibration. The raw frames are combined, dark subtracted and flat fielded, flagging any badpixels in the process. After combining the raw frames, the recipe will attempt to detect the lines. For this purpose, the image is sliced into lines parallel to the wavelength direction. For each slice, peaks belonging to the calibration wavelengths are found and assigned to the corresponding input wavelengths. This is done for each calibration wavelength by searching a window region of +/- ird.wave_calib.line_tolerance around the expected pixel for the peak of the calibration wavelength (assuming a linear dispersion and the minimum and maxmimum wavelengths as specified in the header of the master instrument flat field frame) for the maximum image value. The actual positions for all input calibration lines are stored and a polynomial fit of input calibration lines versus acutal pixel positions is performed and used to interpolate all wavelength values between calibration lines for the image slice. Once all slices inside the spectral region have been processed the PDT is updated with the new information and written out as the product.

3.2.4.1.6 Products:

Name	Туре	Description
IRD_ WAVECALIB	FITS[Im(9)]	The wavelength calibration data. This
		FITS file contains in total six
		extensions, all containing imaging data.
		Each image corresponds to one column
		in the pixel description table (PDT).
		The order is: wavelength, spectra id, slit
		id, wavelength width (or error on
		wavelength), second derivative and
		illumination fraction Additionally
		saved is the image resulting from a
		simple combination of all frames, the
		bad pixel map and an RMS map.

troscopy.outfilename		Please also see the esorex documentation	spectroscopy.fits	
		for naming of output products.		
ird.science_	int	The collapse algorithm to use. $0 =$	0	0,1
spectroscopy.coll_ alg		Mean, $1 = Median$.		

3.2.4.2.5 Description:

This recipe creates the actual science frames for spectroscopy mode. In spectroscopy mode, frames are not dithered and so this recipe performs a simple processing of dark subtraction and flat fielding before using a user specified method to combine the frames. If a atmospheric calibration is provided this is subtracted from the result.

3.2.4.2.6 Known Issues:

The recipe is not using the wavelength calibration file. In order to remove the effects of the wavelength dependence of the flat, the recipe should really use a series of flats taken at different wavelengths and construct a 'super' flat from this using the wavelength calibration file, in the same way as this is done for IFS. However, it is not clear if this is in fact required or if the wavelength dependence of the flat has too small an effect on the spectroscopic data reduction to make it necessary to perfom this wavelength dependent calibration.

		before frame combination. The value		
		expresses the minimum unsuppressed		
		frequency as fraction of total frequency		
		domain radius (a value of 1 would		
		suppress essentially all frequencies).		

3.2.6.1.5 Description:

This recipe uses the Andromeda algorithm (Mugnier et al. 2008) for planet detection. The recipe has been implemented in C following the IDL script obtained from L. Mugnier as much as possible. The basic reduction of raw frames follows that of the other IRDIS science recipes, in particular dark subtraction, flat fielding and frame centering is done as for the science_dbi recipe. Please see the science_dbi recipe for more details. Andromeda can also be used in combination with SDI by switching the use_sdi flag to TRUE. The current version is only a first attempt – please use with care.

3.2.6.1.6 Known Issues:

The recipe result if very sensitive to the input parameter choice and we believe this mayindicate a bug somewhere. We also found that obtaining useful results on some input datais not possible.

3.2.6.1.7 Products:

Name	Туре	Description
IRD_ ANDROMEDA	FITS[Im(4)]	The main science frame. The FITS file
		contains 4 extensions: the image, the
		badpixels, the rms error and a

ird.loci.filter_ radius	double	Filter radius for ADI frame combination. A non zero value leads to suppression of high frequencies in the fourier domain before frame combination. The value expresses the minimum unsuppressed frequency as fraction of total frequency domain radius (a value of 1 would suppress essentially all frequencies).	0.0	0.0-1.0

3.2.6.2.5 Description:

This is LOCI. LOCI is the >>locally optimized combination of images<< algorithm invented by Lafreniere and Marois. The SPHERE implementation follows the paper Lafraniere et al. (2007, ApJ, 660) very closely. Input parameters are named equivalently to the parameters as the appear in the paper. The preprocessing done before the actual LOCI algorithm is applied is the same as that for other IRDIS science recipes (e.g. science_dbi): the raw frames are dark subtracted, flat fielded and centered. It is also possible to runSDI before LOCI, by setting the use_sdi switch to TRUE. Please see the description for the science_dbi recipe for more details on the basic reductions. LOCI itself is implemented as in the original paper without an special tweaks. The step of subtracting the radial profile before LOCI is run as descibed in the paper is currently not implemented. The final output of the recipe is a LOCI image – since no special care is taken for normalisation etc. beware any flux determinations from this image.

3.2.6.2.6 Known Issues:

No support for radial profile subtraction.

3.2.6.2.7 Products:

3.2.8 IRDIS Special notes

3.2.8.1 The Instrument Model

Many IRDIS recipes list IRD_INSTRUMENT_MODEL frames as possible input. These are currently unavailable and and the instrument model, a set of numbers that describe the positions and extents of the two FOVs on the IRDIS detector are usually stored in IRD_FLAT_FIELD frames produced by the sph_ird_instrument_flat recipe. This is the reason why IRD_FLAT_FIELD frames are usually mandatory in all higher-order recipes.

3.2.8.2 Dark and Background Calibration

Most IRDIS recipes accept several types of dark or background products for subtraction:

- IRD MASTER DARK
- IRD INS BG
- IRD INS BG FIT
- IRD SKY BG
- IRD SKY BG FIT

Some fo the recipes require that at least one dark is provided, some runalso without any dark or background frame. For details, look at the recipe descriptions in the subsections above orat the recipe man pages. If more than one dark / background frame are fed into a single recipe, the recipe will select one according to the following logic:

- 1. if IRD SKY BG FIT is provided, this one is chosen
- 2. else if IRD SKY BG is provided, this one is chosen
- 3. else if IRD INS BG FIT is provided, this one is chosen
- 4. else if IRD_INS_BG is provided, this one is chosen
- 5. else if IRD MASTER DARK is provided, this one is chosen
- 6. else an error is thrown, some recipes also continue without subtractingany dark or background.

Note that the else-if chain implies that all otheres are ignored after achoice has been made. For all dark/background products a pre-selection should be made by theuser (or any automatic environment) to select only calibration products with the same DIT and readout mode. For everything axcept the IRD_MASTER_DARK frames, also the filter configuration should be matched!

3.3 IFS

IFS offers two basic modes:

- YH
- YK

The calibration cascade (workflow) is identical for both modes. Care should however be taken that calibration products and raw frames alwayswere taken in the same mode!

3.3.1.1.5 Description:

The gain recipe calculates the gain for the detector and derives a mask of nonlinear pixels. The input is assumed to be a series of data cubes, each containg a single extension with N > 3 planes that each contain a single exposure. The mean count for each input cube should be different either by increasing the intensity of the illumination source or by using different exposure times. Note that in the latter case the recipe only produces the correct output if the detector gain is independent of the read out mode. The gain recipe, as well as the ron recipe, have a special optional preprocessing step, which corrects some possible bias due to readout electronics settings by first subtracting the median of each input cube from each image in the cube. The gain recipe offers algorithms to calculate the gain, one straightforward fitting algorithm and a more complex fitting algorithm that takes the correct number of fowler samples into account. The second algorithm is switched on using the vacca user parameter and is preferable for accurate gain determinations but can currently not be used to calcuate the detector non-linearity. It is therefore recommended to set the user parameter vacca to 1 when an accurate gain measurement is needed but not non-linearity measurement is needed and 0 in all other cases. In particular for pure monitoring purposes to discover trends in the gain the simpler algorithm is sufficient. For both algorithms the general procedure is similar: The recipes calculates the gain by first collapsing all input cubes to create a single mean image and variance image. The collapse algorithm specified (clean mean by default) and algorithm parameters are used for this process. Once a mean and variance image has been determined the median of the mean image and the corresponding variance is taken as one data point. The collection of input cubes then lead to a collection of data points of median and variance, giving measurements of the variance vs. median relation for the detector. This is then fitted using a polynomial of the specified order (usually 1 or 2). The slope of this curve is the inverse of the gain while the offset gives an estimate of the read out noise. Note that the read out noise estimate obtained here may not be accurate. Please use the dedicated ron recipe to obtain a more accurate estimate of the RON. The estimates of gain and ron are written as keywords in the main recipe product FITS file. If the vacca parameter is set, the recipe corrects the fitting coefficients for the different noise properties expected for different fowler samples. For example, for double correlated reads this corrects the ron by a factor of 2. If the vacca parameter is not set. The recipe determines non linear pixels in a second step. This is done by performing the gain fitting procedure above for each individual pixel. The resulting map of the gain is the data in the first extension of the main product FITS file. Note that the pixel-by-pixel gain values are often very noisy and can not be used to obtain precise gain measurements. Many exposures per input cube are needed to perform accurate pixel fitting. If the fitorder specified is larger than 1, the second order (quadratic) coefficient of the individual pixel fits is saved in an additional FITS file. All pixels that have second order quadratic coefficient larger than the threshold parameter are flagged as non-linear and this resulting map of flags is written out as a third FITS file.

3.3.1.1.6 Products:

Name	Туре	Description	
IFS_ GAIN	FITS[Im(4)]	The linear coefficient of the Photon	
		Transfer Curve (PTC) as image. The	
		file contains the gain values in the first	
		extensions. The second extension	
		contains the bad pixels (static input bad	
		pixels), the fourth extension contains	
		the reduced chi-squared values. The	
		third extension is not used and contains	
		a zero image. The header contains the	
		main gain measurement and its rms.

		in each dark cube in this way removes a		
		spurious ramp effect at the beginning of		
		each dark.		

3.3.1.2.5 Description:

This recipe deals with the creation of the master dark calibration frame. Only raw frames are used in this recipe. The dark is created by combining the input raw frames using the collapse algorithm specified (usually the clean_mean algorithm). After all input frames are combined in this way, the badpixels are determined on the result. First a simple thresholding is applied using the parameters min_accepting and max_accepting. Now the resulting master dark is smoothed with a gaussian kernel of the FWHM specified in the smoothing user parameter, if this is set to a postive value. This smoothed version is subtracted from the master dark to remove large scale RMS variations. Then sigma clipping is used with the sigma user parameter. All pixels that are further than the specified sigma value away from the mean are marked as bad. The resulting (unsmoothed) master dark frame is written out, including extensions for badpixels, RMS and an extension giving the number of input (raw) pixels for each output pixel. The hotpixel map is also written out as a separate parameter.

3.3.1.2.6 Products:

Name	Type	Description	
IFS_ MASTER_	FITS[Im(4)]	The resulting master dark frame. This	
DARK		frame contains 4 different image	
		extensions: the image, badpixels, the	
		rms and the weightmap.	
IFS_ STATIC_	FITS[Im(1)]	An optionally written single extension	
BADPIXELMAP		image of the static badpixels. Note that	
		the content is identical to the second	
		extension in the master dark frame.

3.3.1.3.5 Description:

The detector flat field recipe for IFS is very similar to the instrument flat field recipe for IRDIS. The recipe as described here uses input exposures taken with the narrow band or broad band calibration lamps. Several types of flat fields can be produced – in accordance with the calibration plan and the need to have seperate flat field components to provide maximal time stability and flat fielding accuracy. The recipe can be used to create a preamplifier correction flat (which can be used to remove the stripe structure caused by the pre amplifiers), a large scale flat field which is a smoothed flat field and hence only shows large scale structures, and a normal flat field. Experience from the SPHERE Data Centre shows that the IFS MASTER DFF LONG files (both at the various wavelengths and the white one) are sufficient to correct the pixel-to-pixel variation in the detector response. The preamplifier correction flat and the large scale flat field (which contains smoothed bad pixels) are not needed for further processing. The recipe creates master calibration frames, using the input exposures which should be taken as described in the IFS calibration plan. The usual procedure to create a flat field is as follows. All raw frames are read in and dark subtracted. The frames are then corrected for the pre-amplifier variations derived from the input raw data (note that it is currently not possible to skip the pre amplifier correction altogether). This correction is a division operation rather than a subtraction. After this correction, the mean pixel value across the image is determined for all exposures. For every pixel p=(x,y), a set of $m_i, v_i(x, y)$ data pairs are stored with m_i being the mean value of exposure i described above, and $v_i(x,y)$ being the pixel value for pixel p(x,y) in exposure i. The flat field value is defined as the slope c_i of a linear fit F to the data m_i, v_i . The resulting slope represents the response of an individual pixel p(x,y) to illumination relative to the detector mean response. The value will thus naturally be close to 1 and a division by that value will correct for a pixel's deviation from the average detector response. The fit itself is performed either using a maximum likelyhood method or a robust fitting method which minimizes the sum of the absolute value of the deviations rather than the sum of the squares of the deviations (see e.g. Numerical Recipes for the algorithm). The robust fitting method will yield better results when significant outliers (e.g. due to cosmic rays) can be expected, but does not allow anything but linear fits and can hence not be used to assess detector non-linearity. The flat field values are saved as an image as the main product of the

Page: 64/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

recipe. Aditionally, the recipe may also produce as output a map of all pixels that are identified as non-linear. The criteria for non-linearity are set by the user parameters and can be either pixels that have a flat field value outside specified bounds and/or pixels for which the linear fit produces a reduced chi-squared above a given threshold value. For reliable non-linearity flagging using the reduced chi-squared fit many high quality input exposures are needed. In case that a non zero smoothing value was given, a large scale flat is also created by smoothing the flat field with either a gaussian kernel using FFT or a square kernel using the specific CPL filter algorithm. Unless you know what you are doing leave the default method here which is the FFT smoothing.

3.3.1.3.6 Products:

Name	Туре	Description
IFS_ MASTER_	FITS[Im(4)]	The flat field. This is saved as a FITS
DETECTOR_ FLAT_		file with 4 extensions, the flat values,
FIELD		the badpixels (hotpixels and non-linear
		pixels), the rms error on the flat and a
		weightmap. Used if the lamp in use
		cannot be derived.
IFS_ MASTER_	FITS[Im(4)]	Same as above, produced from all input
DFF_ LONG1		raw frames which had LAMP1
		(1.020mum) switched on
IFS_ MASTER_	FITS[Im(4)]	Same as above, produced from all input
DFF_ LONG2		raw frames which had LAMP2
		(1.230mum) switched on

3.3.1.4.5 Description:

This recipe associates the IFS spectra with lenslets and associates pixels with wavelengths. The wavelengths are an initial estimation from the lenslet model and the sph_ifs_wave_calib should be used to refine them. The raw frames are reduced by optionally dark subtracting either a master background or a master dark and by flat fielding and then combined using the combination algorithm chosen (usually the clean mean algorithm). The flat field used can be either a detector flat field, a flat field of the whole instrument (detector+IFU) or any other flat deemed to be useful for this purpose. In most cases a detector flat field obtained with the broad band calibration lamp seems the best choice. After a combined and reduced frame has been produced the following algorithm is applied:

- A thresholding algorithm will determine the spectra regions from the combined frame. From the regions a point pattern is calculated. A point pattern is a list of points. In this case the points are the centers of the regions;
- Calculate the average width of the spectra regions and use it to scale the width and the stretch factors (x and y directions) of the IFS lenslet model;
- A second point pattern is then determined using the (scaled) IFS lenslet model. If a IFS lenslet model was provided in the form of a FITS file with the model parameters as keywords in its header, this model is used, otherwise the default model is used, please see the description of the lenslet model in the section on static calibrations;
- The expected point pattern is compared with the actual one to determine a relative scale and an offset;
- The IFS lenslet model used for the expected pattern is subsequently scaled and shifted accordingly to reflect the new, actual values of scale and position.
- If desired, the distortion is calculated. This may be crucial to ensure correct wavelength calibrations later in the calibration cascade. If distortion is allowed (using the ifs.spectra_positions.distortion parameter) then the recipe will also fit a 2D polynomial of 4th order in x and y directions to the difference between measured and predicted point patterns. The coefficients of this polynomial model are incorporated in the IFS_SPECPOS product and will be used subsequently in all recipes making use of the created lenslet model file.
- For each pixel having coordinates (x, y) an initial wavelength estimation is calculated. For each point the polygon it belongs to is calculated according to the refined model. The polygon can be rotated, therefore a new aligned polygon having the same center, width and height is calculated. The lower y coordinate y_{low} of the aligned polygon is used to calculate the corresponding wavelength $\lambda(y)$:

$$\lambda(y) = (y - 0.5 - y_{low}) \cdot d + \lambda_{min} \tag{3.3}$$

where d is the model dispersion and λ_{min} is the minimum wavelength according to the model;

REF: VLT-TRE-SPH-14690-660/1/0

• A non linear correction is then applied to $\lambda(y)$ if ifs.spectra_positions.correct_nonlin = TRUE:

$$\lambda'(y) = a \cdot \lambda^2(y) + (b+1) \cdot \lambda(y) + c \tag{3.4}$$

where a, b and c are 0.30870, -0.74312, 0.41505 in H mode and 0.67754, -1.4464, 0.75754 in Y mode respectively;

Finally the calculated data (mode, wavelengths, distortion) is used to construct a pixel description table which is saved, together with the corrected lenslet model parameters, as the primary product of this recipe.

3.3.1.4.6 Products:

Name	Type	Description	
IFS_ SPECPOS	FITS[Im(6)]	The resulting pixel description table	
		(PDT) written out as images. The PDT

ifs.instrument_	bool	Controls if the illumination pattern of	0	-
flat.use_ illumination		lenslets is to be taken into account in		
		the cube creation or not. A low level		
		wave-like structure can appear in the		
		result if it is not applied. However,		
		calculation of of the illumination		
		fraction affects the performance of the		
		recipe and so this option should only be		
		enabled if the artefacts adversely affect		
		the results. Note that there is a		
		corresponding option on the		
		ifs_science_dr recipe which should		
		match the chosen option here.		

3.3.1.5.5 Description:

This recipe creates the instrument flat for IFS. The recipe works in two modes: in the first mode, the raw frames from the calibration procedure are used to create a flat field on the detector which includes the effect of the detector response (the detector flat field is NOT divided out). The product created in this mode may be used as a flat field in the spectra positions or wave calib recipe. In the second mode, the pixel description table produced by the spectra positions recipe and updated by wavelength calibration recipe is used as input together with the calibration raw frames to create a flat field of the IFU which has the effect of the detector response removed (i.e. it is divided by the detector flat). The mode to use is decided depending on the parameters set for this recipe and the input files available. In the total flat field mode the recipe reads in the spectra positions file to set the illuminated regions. The recipe then constructs a flat field in the same way as done for sph ifs master detector flat (optionally first subtracting either a master background or a master dark). The resulting frames is then saved as the total instrument flat. Note that this frame has the same dimensions as the detector and is always dithering dependent. In the IFU flat field mode, the wavelength calibration file is used instead of the spectra positions table. First the same steps are carried out as for the total flat mode. However, the wavlength calibration file is then used to first construct a wavelength dependent flat field (also sometimes called a super flat field), making use of the series of master detector flats provided. This frame is then used to flat field the combined raw frames by dividing it out, to give a flat field containing only the IFU (lenslet) contribution. At this stage the frame is still for the detector itself. A lenslet description table is then constructed using the lenslet model as obtained from the header of the input wavelength calibration frame. This lenslet description table now contains the extracted spectra data for all lenslets. These are then collapsed along the wavelength direction (taking the median values) to obtain a flat field value for all lenslets. The primary data product is written out as a viewable interpolated image (which is not generally used further in the cascade) and a table containing the flat field values for all lenslets. This table is used in other recipes when the IFU flat field is to be applied.

3.3.1.6.5 Description:

This is the recipe responsible for calibrating the pixel to wavelength associations for the IFS. The approach taken for the IFS in SPHERE is model based: the initial model as created by the spectra positions calibration recipe is used as input and the observed wavelength calibration frames are used to modify this model, adjusting the pixel to wavelength associations. This approach assumes implicitly that there are no large discrepancies between the model and the actual wavelength associations. Before the wavelength associations are determined, the raw input frames are combined using the specified combination method (mean, clean mean or median). Optionally either a master background or a master dark dark is subtracted and the result is divided by an optional flat field. The recipe then extracts a one dimensional spectrum for each spectral region (as found in the spectra positions recipe). The *i*-th spectrum has wavelengths $w^{(i)}(y)$ and flux $s^{(i)}(y)$ where y is the pixel index in the wavelength direction. Around each of the line l with wavelength w_l as specified in the user input, the flux weighted mean position is determined in a

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 72/220

window around the expected position with a width as specified by the fit window size parameter:

$$y'_{l} = \frac{\sum_{y=y_{min}}^{y_{max}} s(y)^{2} \cdot y}{\sum_{y=y_{min}}^{y_{max}} s(y)^{2}}$$
(3.5)

where $y_{min} = y(w_l) - \Delta w$ if this is positive and $y_{min} = 0$ otherwise, and $y_{max} = y(w_l) + \Delta w$ if this is smaller than the total spectra length in pixels N and $y_{max} = N$ otherwise. The window region should be chosen so as to avoid cases where there is none or more than one sharp line within the region of width $2\Delta w$ around the predicted pixel for the wavelength w_l . Once parameters y_l' have been determined for all $l = 1..n_l$ for a spectrum, a polynomial fit is performed to the y_l' vs. w_l data. This polynomial is then used to fill in the wavelength associations for all pixels in the region of that spectrum. More specifically, for the i-th spectrum a vector of wavelengths $w_c^{(i)}(y)$ is generated associating the y-th pixel with the corresponding wavelength. In cases when no fitting was possible (for example due to the fact that not enough identifiable lines were present in the spectra region) or if the resulting wavelength associations for the minimum and maximum wavelengths of the spectrum is different by more than 3 times the dispersion to the expected value, the assigned wavelengths of the model are used (even if a new association was found). In case no spectrum could be extraced in the first place, all wavelengths are set to zero and all pixels in the spectra region thereby marked as bad. Hence, ignoring the spectra marked as bad regions, for the i-th spectrum the final wavelengths vector $w_f^{(i)}$ is:

$$w_f^{(i)} = \begin{cases} w^{(i)} & \text{if } w_c^{(i)} \text{ deviates too much from } w^{(i)} \\ w_c^{(i)} & \text{otherwise} \end{cases}$$
(3.6)

And for every i-th spectrum the following QC values are calculated:

- $w_{min}(i) = \min w_f^{(i)}$
- $w_{MAX}(i) = \max w_f^{(i)}$
- $w_{cent}(i) = w_f^{(i)}(\frac{N-1}{2})$

Finally the resolving power $r_p^{(i)}(y)$ of the *i*-th spectrum is calculated as follows:

$$r_p^{(i)}(y) = \frac{w_f^{(i)}(y) + w_f^{(i)}(y+1)}{2(w_f^{(i)}(y+1) - w_f^{(i)}(y))}$$
(3.7)

lastly the median resolving power for the i-th spectrum is:

$$r(i) = \operatorname{median}(r_n^{(i)}) \tag{3.8}$$

When all spectra have been processed in this way, the final, now corrected, pixel description table is written out as the main recipe product. Several quality control keywords are provided in the header to help monitor the quality of the calibration. In particular:

- "ESO QC MEDIAN DISPERSION" = $d_m = \text{median}(d)$, where d is the dispersion image related to the output pixel description table;
- "ESO QC MEDIAN RESOLVING POWER" = median(r(i)).
- "ESO DRS MEDIAN MIN WAVEL" = $median(w_{min}(i)) \frac{d_m}{2}$
- "ESO DRS MEDIAN MAX WAVEL" = $median(w_{MAX}(i)) + \frac{d_m}{2}$;
- "ESO DRS MEDIAN CENT WAVEL" = $median(w_{cent}(i))$.

Page: 73/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

As of SPHERE 0.42.0b, an additional resolving power calculation is performed as follows:

- A median collapse spectrum is formed from the IFS_WAVECALIB_CUBE product by computing the median of the good pixels in each plane of the cube (excluding the 60 pixels closest to each image edge);
- A Gaussian fit is made to each of the laser lamp arc lines in the median collapse spectrum (3 lines in YJ, 4 in YJH). The fit is made in flux as a function of pixel coordinate along the spectrum;
- A linear fit is then made between the known wavelengths of the laser lamp arc lines as a function of the fitted pixel coordinate of those lines.

From these calculations, the following header keywords are populated and saved in both the IFS_WAVECALIB and IFS_WAVECALIB_CUBE products:

- ullet The integrated flux of laser line n is stored as ESO QC FLUX LASERn;
- The resolving power of laser line n (i.e., λ_0/Δ_λ , where λ_0 is the nominal wavelength of the laser lamp and Δ_λ is the FWHM of the Gaussian fit) is stored as ESO QC RESPOW LASERn;
- The wavelength-to-pixel scale, i.e. the gradient of the linear fit described above, is stored as ESO QC DISPERSION;
- The RMS value of the linear fit described above (formally, the coefficient of determination, commonly referred to as R^2), is stored as ESO QC DISPERSION RMS.
- The wavelength in pixel 1 (i.e. the first pixel), as determined by the linear fit described above, is stored as ESO QC MIN LAMBDA.

3.3.1.6.6 Products:

Name	Type	Description
IFS_ WAVECALIB	FITS[Im(7)]	The calibrated pixel description table

3.3.1.7.5 Description:

This recipe creates a table with centre star positions. The input raw frames are each reduced by subtracting the dark and applying the flat provided. After sorting the frames, the recipe only reduces the image data of the waffle images. An optional mask frame may be given, of the same dimensions as the raw input frames, which allows masking out of regions before the point sources are detected. This can mainly be used on images where despite use of a coronagraph a significant central signal is present. The left and right parts of the illuminated detector regions are extracted and left and right part are seperately analysed using a aperture detection algorithm. The aperture detection algorithm detects all connected regions of at least 4 pixels size (area) that are the given sigma above the background. The so detected waffle stars are then used to contruct a geometric centre of all stars found. This is then the frame centre. The recipe also works for the case that there is only one star (e.g. the coronograph is out and no waffle stars are formed). After frame centers have been determined for all waffle images an internal table is created with an entry for each waffle image, giving the time of the start of the exposure and the centre information. The recipe reads the position of the IFS DMS from the header of the raw frames, divides by 18.0 to convert from micron to pixels, and stores them in the output table.

3.3.1.7.6 Known Issues:

While this recipe is functional, its requirements are fully settled. The recipeimplementes the current baseline of how star centering is foreseen in IFS.

3.3.1.7.7 Products:

ifs.science_	double	The bin size to use for the creation of	20.0	-
dr.xtalkco.stephist		the pixel histogram for the most likely		
		value find. The most likely value is		
		found in each subwindow and the		
		smmothed version of these subtracted		
		from the originial.		
ifs.science_	double	The absolute threshold for badpixel	100.0	-
dr.badpixco.threshold		correction to use. This is applied in a		
		logical AND operation with the badpixel		
		correction factor threshold. Any pixels		
		above this value, that are also above		
		badpixco.fac * median, are set to the		
		median of the surrounding 8 pixels.		
ifs.science_	double	The absolute threshold factor for	5.0	-
dr.badpixco.fac		badpixel correction to use. This is		
		applied in a logical AND operation with		
		the absolute badpixel correction		
		threshold. Any pixels above		
		badpixco.fac * median AND also above		
		the absolute threshold, are set to the		
		median of the surrounding 8 pixels.		
ifs.science_	int	The border size in pixel to ignore for the	100	-
dr.badpixco.border		purpose of badpixel correction.		

3.3.1.8.5 Description:

This is the science calibration recipe for IFS. The input raw observation frames are reduced by dark subtracting each one, if a master background or alternatively a master dark frame is given as input. Also, in case a pre-amplifier correction frame (basically for de-striping) the raw frames are corrected for the stripes. The large scale effects are then corrected by creating a so called super flat that combines the (large scale) flat fields taken with different colour lamps into a single flat field that takes the pixel to wavelength correspondence into account using the information from the input wavelength calibration file. After dividing out the super flat, a broad band flat field that should have been created from recent data is divded out to remove the (small scale) flat variations that are very time dependent. Note that this broad band master flat field should already be corrected for the large scale flat structure. This means it must have been created using the master flat field recipe with a large scale flat as input. The recipe allows automatic combination of images using the spec deconv and simple adi routines. These reduction steps can be selective switched on or off. To combine frames manually, the recipe the use adi and spec deconv flags should be set to false. Note that the ADI and spectral deconvolution routines currently use fixed parameters as noted. The correction of (detector pixel-to-pixel) correction can be switched on by the appropriate flag. It is strongly recommended to use only the small-scale correction. The largescale variant is a bit over-aggressive and deprecated. The correction of detector-level badpixels can also be switched on with a flag. This will interpolate over badpixels to substitute their values instead of relying on dithering.

ifs.detector_	double	The threshold for detection of dark	1000.0	-
persistence.threshold_		regions. All regions with pixels below		
lower		this value in the unsaturated image		
		(with lamp on) are masked as dark		
		regions in all other input frames.		

3.3.1.9.5 Description:

This recipe determines the detector persistence, by measuring the signal fall-off rate. The input raw frameset should contain frames taken with the illumination source on as well as off. Specifically, there should be at least one exposure containing a significant number of saturated pixels, at least one exposure containing illuminated (but not saturated pixels) and exposures with the source switched off. The exposures with illumination off should be taken in rapid succession immediately after the source is turned off. Frames are ordered in time sequence by the recipe, optionally a hotpixel mask from a master dark or a seperate image is used to mask bad pixels. As a first step, a simple thresholding algorithm is used on the illuminated but **unsaturated** image to determine illuminated and unilluminated pixel sets, P_i and P_u . For each of the unilluminated frames,the mean for the unilluminated pixels $< P_u >$ is subtracted from the mean of the illuminated pixels giving $P(t) = < P_i > (t) - < P_u > (t)$. The series of P(t) values is then fit assuming a polynomial behaviour in 1/t, that is, assuming $P(t) = c_0 + c_1 \times 1/t + c_2 \times 1/t^2 + ...$. Up to which coefficient the fit is to be performed is set using the fitorder user parameter. A copy of the input illuminated but not saturated frame is saved as the main recipe product. The relevant persistence measurements are written as keywords into the product header.

3.3.1.9.6 Products:

Name	Type	Description	
IFS_ DETECTOR_	FITS[Imcube(4)]	A FITS cube with the fitting coefficients	
PERSISTENCE		for each pixel. The fitting coefficients	
		are for a polynomial fit of log(count) vs.	
		log(time). Each plane in the image cube	
		contains the values of one polynomial	
		coefficient (starting with the constant	
		term).	

3.3.1.10 sph_ifs_cal_background

background.smooth		combined image. The value gives the		
		FWHM of the gaussian that the		
		combined image is convolved with to		
		smooth it. Set the value to zero to		
		switch smoothing off completely.		
ifs.cal_	int	The number of samples to use for a	1000	0-1000000
background.nsamples		polynomial 2D fit. Only used if the fit		
		parameter is set.		

3.3.1.10.5 Description:

This recipe creates a summed, optionally dark subtracted frame that is mainly useful for background measurements. The raw input frames must carry the IFS_CAL_BACKGROUND_RAW tag. The dark frame is optional and will be subtracted from the resulting frame if porovided. Static badpixels are determined using the sigma_clip user parmameter – an OR combination is used with the badpixels in the master dark frame if one if provided. The resulting background map is divided by the exposure time to give a result in counts per second. If a dark was provided the exposure time of this dark is subtracted from the total exposure time before. In case the smooting parameter is set to a value above 0, the resuling combined frame is smoothed (after all badpixels have been interpolated). If so desired, a 2D polynomial fit to the measured (possibly smoothed) bacground is also written out as a second product.

map.add_ rotation		measured point pattern is rotated by		
		before attempting a match. This is		
		applied in addition to the rotations		
		specified in the lenslet model in the		
		keywords of the calibration input files.		
		The sense of direction is specified in the		
		same sense as in the lenslet model.		

3.3.1.11.5 Description:

This recipe measures the distortion of the lenslet grid. The input raw frames are first reduced in the same way as for the science_dr recipe (allowing dither but no frame rotation), optionally including dark subtraction via either a master background or a master dark and optionally (if all flats provided) flat fielding. The resulting monochromatic images are then collapsed along the wavelength direction giving a single image. This image is then analysed to detect the point sources using simple thresholding, taking the user parameter as the threshold value (sigmas). Now the way the recipe proceeds depends on the inputs. If no input point pattern has been provided, the recipe will construct one from the reduced images detected point sources. This will then be written out as a product. If a input point pattern was provided, the recipe will skip this step and proceed directly to the measurement of the distortion. Please note that the distortion is measured in any case which means that the output distortion should be zero in case that no input point pattern was provided. The distortion map is constructed by comparing the detected point sources position with the expected point source position as provided in the input point pattern. Each comparison is done with the closest point found and yields one distortion vector. Upon

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 85/220

completion, all distortion vectors that have a length larger than the max_distortion specified as a user parameter will be removed before the x and y components of the distortion vectors will be fit with a 2D polynomial (of the user specified fitting order). To allow for easier quality control, the recipe provides a user flag for a self consistency check. If this flag is set, the recipe will now apply the measured distortion map to the input raw data and calculate any residual distortion left. This residual is written out as an extra FITS file – it should be visually inspected to verify that the distortion map has been calculated with sufficient accuracy in the detector region(s) of interest.

3.3.1.11.6 Products:

Name	Type	Description
IFS_ POINT_	FITS[Table]	The point pattern as obtained from the
PATTERN		input images. Only written in case that
		an input point pattern was provided.
		This product may be used as reference
		input for future runs of this recipe.
IFS_ DISTORTION_	FITS[Im(8)]	The distortion map. The distortion map
MAP		is saved as an 8 extension FITS file with
		the first 4 extensions containing the
		distortion in the x direction, the
		badpixels, the rms on the distortion in x
		and a weightmap. The second set of 4
		extensions contain the same information
		but for the distortion in the y direction.

3.3.2 IFS Workflow Summary

The IFS workflow is summarized in Fig.3.5

3.3.3 IFS Special Notes

The IFS calibration cascade is currently under heavy revision. It is thus actually not recommended to draw information on the actual workflowfrom this version of the manual! the individual recipe descriptions above are up to date and accurate, but the overall workflow will change considerable over the next weeks!

3.4 ZIMPOL

ZIMPOL offers the following basic observing modes:

- Imaging
- P1 polarimetry
- P23 polarimetry

These have their own science recipes and a number of dedicated calibrations. Additionally, ZIMPOL has different operational modes:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 86/220

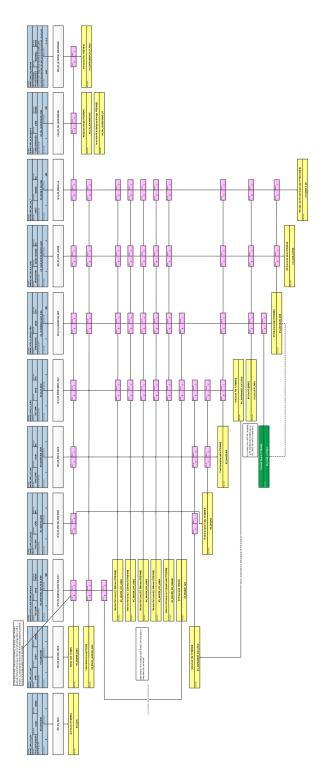

Figure 3.5: Summary of the IFS calibration cascade (workflow)

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 87/220

• FastPol

- SlowPol
- Window

These do not affect the choice or the order of the calibration workflow, but data taken in any of these sub-modes should not be mixed with data from other sub-modes in a single cascade!

3.4.1 ZIMPOL Imaging Calibrations and Science

These are calibration that apply to the IMAGING mode of ZIMPOL.

3.4.1.1.5 Description:

This recipe performs pre-processing steps for the raw data in the imaging modes. The pre-

Page: 89/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11

processing is an utility recipe and should be only used by off-line data reduction. The raw frame cube in the imaging mode is two extensions fits-files with the following format:

- first extension represents data cube of NDITS frames from camera-1 for a given DIT, including overscan area of 2 ADUs;
- second extention represents data cube of NDITS zimpol frames from camera-2 for a given DIT, including overscan area of 2 ADUs.

No other frame is used in this recipe. In the imaging detector mode each raw frame contains 2-interlaced sub-frames, but the useful imaging component is only kept in the first sub-frame because the second one is masked (it can be considered as a dark current). The input raw cube frame, which should carry SPH_ZPL_TAG_PREPROC_IMAGING_RAW tag, are read first and then the following pre-processing steps are performed:

- 1. extract each camera from the each extension ("two camera cubes");
- 2. combine the 2 detector segments (ADU) into a single image »trim away« prescan/overscan areas;
- 3. split into even and odd sub-frames;
- 4. for each initial raw image create a plane with two extensions (informative component intensity, dark current);
- 5. create an output fits files with two images extension and one binary table extension with the computed mean values of the overscan bias level and its rms (4 cols).

Since the zimpol frame is square, splitting the two sub-frames yields to the 1:2 aspect ratio. The pre-processing imaging output product is written out in the two fits-cube files (camera-1 and camera-2) with the ZPL EXP IMAGING format specified as follows:

- odd sub-frame image (informative component);
- even sub-frame image (dark current component);
- table of mean overscan bias level values and its rms (4 cols):
 - [1-col, 2-col] ADU1 OVSC MEAN & ADU1 OVSC RMS
 - [3-col, 4-col] ADU2 OVSC MEAN & ADU2 OVSC RMS

These pre-processing imaging products may be used in all subsequent imaging recipes.

3.4.1.2.5 Description:

This recipe creates the master bias calibration frame for the imaging mode. The input frames might be either bias raw frames with the ZPL_BIAS_IMAGING_RAW tag or preprocessed bias frames, which should carry the ZPL_BIAS_IMAGING_PREPROC_CAM1 and/or ZPL_BIAS_IMAGING_PREPROC_CAM2 tags. No other frames are used in this recipe. If input frames are raw frames then the master bias recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph_zpl_preproc_imaging for the detailed description of the pre-processing). The master bias for each camera is then created by combining pre-processed frames (= all planes) from the imaging pre-processed cube(s) using a specified collapse algorithm (usually the clean_mean algorithm, defined as a default one). If the flag >>subtract_overscan<< is not set up to 0, the recipe subtracts (before combining) the overscan bias level from the pre-pocessed cube(s) individually for each plane. Otherwise, the overscan subtraction step is skipped. (The overscan bias level - >>ADU1 mean overscan value<< from the left area of the image and

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 92/220

>>ADU2 mean overscan value<< from the right area of the image – for odd and even sub-frames are saved anyway as a binary table in the imaging pre-processed cube(s)). After all pre-processed frames (all 4 zimpol exposure sub-frames) are combined in this way, the badpixel maps are determined on the result, using a simple sigma clipping algorithm. It sets the bad/hot pixels to be all those that are further than the >>specified sigma x the total RMS<< of the whole image away from the image median. The resulting master dark frames for both cameras are written out in the DOUBLE IMAGE (8 extensions) format specified as follows:

- 1. odd sub-frame (informative component):
 - master bias image,
 - badpixel-map,
 - ncomb-map,
 - rms-map;
- 2. even sub-frame (dark current component):
 - master bias image,
 - badpixel-map,
 - ncomb-map,
 - rms-map.

Note that the default parameter for the sigma clipping >>sigma_clip<< is set up to 0. In this case the recipe will not detect >>hot/bad pixels<<, so all pixels will be considered as good ones in the product. Usually, the zpl exposure imaging frames have the two vertical pixel stripes with strong >>bias<< signal. If the >>sigma_clip<< parameter is not 0, these pixels will be detected as bad ones and will be excluded from the subsequent treatment in the sphere pipeline (according to the sphere pipeline concept the detected bad pixel is marked as a bad in the badpixel-map and its rms value set to the 1e10 in the rms-map). Therefore, using the master bias for all subsequent imaging recipes in the default case (no sigma clipping), will preserve the signal in the vertical pixels stripes. The master imaging bias products are used in all subsequent imaging recipes.

ZPL DARK IMAGING PREPROC CAM2 tags, and master bias frames (if any) with the ZPL MASTER BIAS IMAGING CAM1 and/or ZPL MASTER BIAS IMAGING CAM2 tags. If input frames are raw frames then the master dark recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc imaging for the detailed description of the pre-processing step). The master imaging dark for each camera is then created by combining pre-processed frames (= all planes) from imaging pre-processed cube(s) using a specified collapse algorithm (usually the clean mean algorithm, defined as a default one). If the flag >>subtract overscan<< is not set up to 0, the recipe subtracts (before combining) the overscan bias level from the pre-pocessed cube(s) individually for each plane. Otherwise, the overscan subtraction step is skipped. (The overscan bias level - >>ADU1 mean overscan value << from the left area of the image and >>ADU2 mean overscan value << from the right area of the image – for odd and even sub-frames are saved anyway as a binary table in the imaging pre-processed cube(s)). After all pre-processed frames (all 2 zimpol imaging exposure sub-frames) are combined in this way, the badpixel maps are determined on the results, using a simple sigma clipping algorithm. It sets the bad/hot pixels to be all those that are further than the >>specified sigma x the total RMS<< of the whole image away from the image median. The resulting master dark imaging frames for both cameras are subtracted by the corresponding master bias imaging calibrations and written out in the DOUBLE IMAGE (8 extensions) format specified as follows:

- 1. odd sub-frame (informative component):
 - master dark image,
 - badpixel-map,
 - \bullet ncomb-map,
 - \bullet rms-map;
- 2. even sub-frame (dark current component):
 - master dark image,
 - badpixel-map,
 - ncomb-map,
 - rms-map.

The master imaging dark products are used in the all subsequent imaging recipes.

3.4.1.4.5 Description:

The recipe creates the intensity flat field calibration frames for the imaging modes. The input frames might be either intensity flat raw frames with the ZPL_INT_FLAT_IMAGING_RAW tag or pre-processed intensity flat frames, which should carry the ZPL_INT_FLAT_IMAGING_PREPROC_CAM1 and/or ZPL_INT_FLAT_IMAGING_PREPROC_CAM2 tags, and master bias frames (if any) with the ZPL_MASTER_BIAS_IMAGING_CAM1 and/or ZPL_MASTER_BIAS_IMAGING_CAM2 tags, and and master dark frames (if any) with the ZPL_MASTER_DARK_IMAGING_CAM1 and/or ZPL_MASTER_DARK_IMAGING_CAM2 tags. If input frames are raw frames then the intensity flat field recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph_zpl_preproc_imaging for the detailed description of the pre-processing step). There are two

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 99/220

main different methods to calculate the master intensity flatfield:

- combining frames (plus normalizing): in this case, the raw frames must be acquired with the same DIT and filter;
- linear fitting method of the individual pixels: in this case, the raw frames must be acquired either with a different DIT or with a different intensity of the lamp, but with the same filter.

The first <combining frames method> combines pre-processed raw intensity flatfield frame (= all planes) from the pre-processed cube(s) using the specified collapse algorithm (usually the clean_mean algorithm, defined as a default one). After all pre-processed frames (all 4 zimpol exposure sub-frames) are combined in this way, the badpixel maps are determined on the results, using a simple sigma clipping algorithm. It sets the bad/hot pixels to be all those that are further than the >>specified sigma x the total RMS<< of the whole image away from the image median. Note that the badpixels that are stored in the master flat field itself as produced by this recipe contain all the badpixels (for each sub-frames individually) at this point in the cascade (i.e. badpixels from the master dark and master bias, if exists). The resulting master intensity flat field products for both cameras are then written out in the fits files in the DOUBLE IMAGE format:

- 1. zpl exp imaging odd sub-frame (informative component):
 - intensity flat field image,
 - badpixel-map,
 - ncomb-map,
 - rms-map;
- 2. zpl exp imaging even sub-frame (dark current component):
 - intensity flat field image
 - badpixel-map
 - ncomb-map
 - rms-map;

The second linear fitting flat fielding procedure> descibed below (identical to that for the IFS and IRDIS) is then applied to the each >>zpl exp imaging sub-frames<< (odd - informative component, even-dark current component) separately.

- 1. The mean value is determined for the respective sub-frame for all exposures.
- 2. For every pixel p = (x, y), a set of $m_i, v_i(x, y)$ data pairs are stored with m_i being the exposure mean value and $v_i(x, y)$ being the pixel value for exposure i.
- 3. The flat field value is defined as the slope c_i of a linear fit F to the data m_i, v_i .
- 4. The fit itself is performed either using a maximum likelyhood method or a robust fitting method which minimizes the sum of the absolute value of the deviations rather than the sum of the squares of the deviations (see e.g. Numerical Recipes for the algorithm). The robust fitting method will yield better results when significant outliers (e.g. due to cosmic rays) can be expected.
- 5. The flat field values (linear coefficients) are saved as an image as the main product of the recipe in the same DOUBLE IMAGE format (see above).

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 100/220

Aditionally, the recipe may also produce a separate output of all pixels that are identified as non-linear. The criteria for non-linearity are set by the user parameters and can be either pixels that have a flat field value outside specified bounds and/or pixels for which the linear fit produces a reduced chi-squared above a given threshold value. For reliable non-linearity flagging using the reduced chi-squared it is necessary to use many high quality input exposures. Since the badpixel treatment is somewhat complicated, some important points: the badpixels that are stored in the master flat field itself as produced by this recipe contain all the badpixels (for each sub-frames individually) at this point in the cascade. Pixels that were marked as bad from the input static badpixel map are also marked as bad here. The optional static badpixel output that is produced contains strictly only those pixel that the flat field recipe itself deemed to be bad. This does not necessarily include all the badpixels from the static badpixel input file. The intensity flat field calibration products for both cameras my be used in all subsequent imaging mode recipes if one needs to remove the pixel to pixel variation of the signal response on the detector.

3.4.1.5.5 Description:

The recipe determines the position of starcenters the imaging science input frames might be either imaging raw frames ZPL STAR CENTER IMG RAW pre-processed tag or imaging science frames, ZPL STAR CENTER IMG PREPROC CAM1 should carry $_{
m the}$ and/or ZPL STAR CENTER IMG PREPROC CAM2 tags, and master bias frames (if any) with the ZPL_MASTER_BIAS_IMAGING_CAM1 and/or ZPL_MASTER_BIAS_IMAGING_CAM2 tags, and and master dark frames (if any) with the ZPL MASTER DARK IMAGING CAM1 and/or ZPL MASTER DARK IMAGING CAM2 tags, and intensity flat field frames (if any) with the ZPL INT FLAT IMAGING CAM1 and/or ZPL INT FLAT IMAGING CAM2 tags. If input frames are raw frames, then the recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc imaging for the detailed description of the pre-processing step). The pre-processed star center frames are then calibrated (for each camera) by subtracting the master imaging bias and the master imaging dark, and divided by the corresponding intensity imaging flat field. The calibrated frames are de-dithered and then saved as intermediate products. The next step is to combine all these calibrated and de-dithered frames, using a standard mean algorithm. The combined frames for both cameras are of the DOUBLE IMAGE (8 extensions) format specified as follows: - combined intensity star-center image, badpixel-map, ncomb-map and rms-map. - combined star-center dark image (dark current), badpixel-map, ncomb-map and rms-map. The combined star center frame is then analysed using an aperture detection

Page: 104/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

algorithm: - The aperture detection algorithm detects all connected regions of at least 4 pixels size (area) that are the given sigma above the background. - The so detected waffle stars are then used to contruct a geometric centre of all stars found. This is then the frame centre. The recipe also works for the case that there is only one star (e.g. the coronograph is out and no waffle stars are formed). The coordinates of the detected frame centers are added as the keywords in the header of the output fits-file products for each camera: - DRS ZPL STAR CENTER IFRAME XCOORD; - DRS ZPL STAR CENTER IFRAME YCOORD; - DRS ZPL STAR CENTER PFRAME YCOORD. This star center calibrated products for each camera should be used in the science imaging recipe.

3.4.1.5.6 Products:

Name	Type	Description
ZPL_STAR_	FITS[Im(8)]	The final combined star center frame of

3.4.1.6.5 Description:

The recipe reduces combined science frames for the imaging modes. The input frames might be either science imaging raw frames $_{
m with}$ the ZPL SCIENCE IMAGING RAW tag or pre-processed science imaging frames, ZPL_SCIENCE_IMAGING_PREPROC_CAM1 should carry the ZPL_SCIENCE_IMAGING_PREPROC_CAM2 tags, and master bias frames (if any) with the ZPL MASTER BIAS IMAGING CAM1 and/or ZPL MASTER BIAS IMAGING CAM2 tags, and and master dark frames (if any) with the ZPL MASTER DARK IMAGING CAM1 and/or ZPL MASTER DARK IMAGING CAM2 tags, and intensity flat field frames (if any) with the ZPL INT FLAT IMAGING CAM1 and/or ZPL INT FLAT IMAGING CAM2 tags. If input frames are raw frames, the science imaging recipe first performs the pre-processing

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 108/220

step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph_zpl_preproc_imaging for the detailed description of the pre-processing step). The pre-processed imaging science frames are then calibrated (for each camera) by subtracting the master imaging bias and the master imaging dark, and divided by the corresponding intensity imaging flat field. The calibrated frames are de-dithered and de-rotated and then saved as intermediate products. Note: the calibration frames with SPH_ZPL_TAG_STAR_CENTER_IMG_CALIB_CAM1(CAM2) tags provide the center coordinates to rotate around. If these calibrations are not presented the center of the frames will be used (normally, xc=yc=512 pixel). The final step is to combine all these calibrated, de-dithered and de-rotated frames, using a standard mean algorithm. The combined frames for both cameras are of the DOUBLE IMAGE (8 extensions) format specified as follows: - combined intensity science image, badpixel-map, ncomb-map and rms-map. - combined science dark image (dark current), badpixel-map, ncomb-map and rms-map. The output double image frames are reduced pipeline data products for both cameras. Some additional notes:

• For a point-source an estimate of the Strehl ratio may be useful. The presence of a filter table frame will enable the estimation, which on failure will do nothing and on success will insert Strehl related QC parameters for both cameras into the product headers related to the second camera.

cam1		pre-processed raw data for CAMERA-1.	1.fits	
zpl.preproc.outfilename_	string	The output postfix-filename of the	preproc_ cam_	-
cam2		pre-processed raw data for CAMERA-2.	2.fits	

3.4.2.1.5 Description:

This recipe performs pre-processing steps for the raw data in the polarimetric modes. The preprocessing is an utility recipe and should be only used by off-line data reduction! The raw frame in the polarimetric modes are two extensions fits-file format:

- first extension represents data cube of NDITS frames from camera-1 for a given DIT, including prescan /overscan area of 2 ADUs;
- second extension represents data cube of NDITS zimpol frames from camera-2 for a given DIT, including prescan / overscan area of 2 ADUs.

No other frame is used in this recipe. In all polarimetric ZIMPOL modes (P1,P2,P3) detector mode is always double-phase mode. In the double-phase detector mode one single ZIMPOL-exposure is output of two consecutive images/frames from one CCD:

- the 1 image is the k-th ZIMPOL frame recorded at phase one=Phase 0
- the 2 image is the k+1 ZIMPOL frame recorded at phase one=Phase PI

Each frame contains 2-interlaced sub-frames, storing 2 complimentary polarization component images. The input raw cube frame should carry SPH_ZPL_TAG_PREPROC_RAW tag is read first and then the following pre-processing steps are performed:

- 1. extract each camera from the each extension (*) two camera cubes (*);
- 2. combine the 2 detector segments (ADU) into a single image »trim away« prescan/overscan areas from images;
- 3. compute the mean overscan bias level from the overscan areas;
- 4. cut junk rows for Phase 0 (one bottom and one upper *binned pixel < row);
- 5. cut junk rows for Phase PI (two upper »binned pixel«);
- 6. split into even and odd sub-frames;
- 7. for each two single raw images (phase 0 and pi) create a plane with 4 extensions;
- 8. create an output fits files with four images extension and one binary table extension with the computed mean values of the overscan bias level and its rms (8 cols).

Since the zimpol frame is square, splitting the two sub-frames yields to the 1:2 aspect ratio. The output product is two fits-cube files (camera-1 and camera-2) of the ZPL EXP format specified as follows:

- phase zero odd sub-frame image;
- phase zero even sub-frame image;

Page: 111/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

• phase PI odd sub-frame image;

- phase PI even sub-frame;
- table of mean overscan bias level values and its rms (8 cols):
 - [1-col, 2-col] ADU1 ZERO PHASE OVSC MEAN & ADU1 ZERO PHASE OVSC RMS
 - [3-col, 4-col] ADU2 ZERO PHASE OVSC MEAN & ADU2 ZERO PHASE OVSC RMS
 - **[5-col, 6-col]** ADU1 PI PHASE OVSC MEAN & ADU1 PI PHASE OVSC RMS
 - [7-col, 8-col] ADU2 PI PHASE OVSC MEAN & ADU2 PI PHASE OVSC RMS

These pre-processing products may be used in all subsequent polarimetric recipes.

3.4.2.1.6 Products:

Name	Type	Description

3.4.2.2.5 Description:

This recipe creates a master bias calibration product for all polarization modes. input frames might be either bias raw frames with the ZPL BIAS RAW tag or preprocessed bias frames, which should carry the ZPL BIAS PREPROC CAM1 and/or ZPL BIAS PREPROC CAM2 tags. No other frames are used in this recipe. If input frames are raw frames then the master bias recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc for the detailed description of the pre-processing). The master bias for each camera is then created by combining pre-processed frames (= all planes) from the pre-processed cube(s) using a specified collapse algorithm (usually the clean mean algorithm, defined as a default one). If the flag >>subtract overscan<< is not set up to 0, then the recipe subtracts (before combining) the overscan bias level of the pre-processed cube(s) individually for each plane. Otherwise, the overscan subtraction step is skipped. (The calculated overscan bias levels - >> ADU1 mean overscan value << from the left area of the image, and >> ADU2 mean overscan value << from the right area of the image – for each phase (0 and pi) are saved anyway as a binary table in the pre-processed cube(s)). After all pre-processed frames (all 4 zpl exposure sub-frames) are combined in this way, the badpixel maps are determined on the result, using a simple sigma clipping algorithm. It sets the bad/hot pixels to be all those that are further than the >>specified sigma x the total RMS<< of the whole image away from the image median. The resulting master dark frames for both cameras are written out in the SPH QUAD (16 extensions) format specified as follows:

- 1. zpl exp phase zero odd sub-frame:
 - master bias image,
 - badpixel-map,
 - ncomb-map,
 - rms-map;
- 2. zpl exp phase zero even sub-frame:
 - master bias image
 - badpixel-map
 - ncomb-map
 - \bullet rms-map;
- 3. zpl exp phase PI odd sub-frame:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 114/220

• master bias image,

- badpixel-map,
- ncomb-map,
- rms-map;
- 4. zpl exp phase PI even sub-frame:
 - master bias image,
 - badpixel-map,
 - ncomb-map,
 - rms-map.

Note that the default parameter for the sigma clipping >>sigma_clip<< is set up to 0. In this case the recipe will not detect >>hot/bad pixels<<, so all pixels will be considered as good ones in the product. Usually, the zpl exposure frames have the two vertical pixel stripes with strong >>bias<< signal. If the >>sigma_clip<< parameter is not 0, these pixels will be detected as bad ones and will be excluded from the subsequent treatment in the sphere pipeline (according to the sphere pipeline concept the detected bad pixel is marked as a bad in the badpixel-map and its rms value set to the 1e10 in the rms-map). Therefore, using the master bias for all subsequent polarimetric recipes in the default case (no sigma clipping), will preserve the signal in the vertical pixels stripes. The master polarimetric bias products may be used in the all subsequent polarimetric recipes.

ization modes. The input frames might be either intesity flat raw frames with the ZPL_INT_FLAT_FIELD_RAW tag or pre-processed intensity flat frames, which should carry the ZPL_INT_FLAT_PREPROC_CAM1 and/or ZPL_INT_FLAT_PREPROC_CAM2 tags, and master bias frames (if any) with the ZPL_MASTER_BIAS_CAM1 and/or ZPL_MASTER_BIAS_CAM2 tags, and master dark frames (if any) with the ZPL_MASTER_DARK_CAM1 and/or ZPL_MASTER_DARK_CAM2 tags. If input frames are raw frames then the intensity flat recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph_zpl_preproc for the detailed description of the pre-processing step). The recipe creates for both cameras the intensity flat field calibration frame, using the input exposures which should be taken as described in the zimpol calibration plan. There are two main different methods to calculate the master intensity flatfield:

- combining frames (plus normalizing): in this case, the raw frames must be acquired with the same DIT and filter;
- linear fitting method of the individual pixels: in this case, the raw frames must be acquired either with a different DIT or with a different intensity of the lamp, but with the same filter.

The first <combining frames method> combines pre-processed raw intensity flatfield frame (= all planes) from the pre-processed cube(s) using the specified collapse algorithm (usually the clean_mean algorithm, defined as a default one). After all pre-processed frames (all 4 zimpol exposure sub-frames) are combined in this way, the badpixel maps are determined on the results, using a simple sigma clipping algorithm. It sets the bad/hot pixels to be all those that are further than the >>specified sigma x the total RMS<< of the whole image away from the image median. Note that the badpixels which are stored in the master flat field product itself will contain all badpixels, accumulated at this point in the cascade (i.e. badpixels from the intensity flat and master dark, and master bias, if exists). The quad image intensity flat field products for both cameras are then written out in the fits files in the QUAD IMAGE format:

- 1. zpl exp phase zero odd sub-frame:
 - intensity flat field image,
 - badpixel-map,
 - ncomb-map,
 - rms-map;
- 2. zpl exp phase zero even sub-frame:
 - intensity flat field image
 - badpixel-map
 - ncomb-map
 - rms-map;
- 3. zpl exp phase PI odd sub-frame:
 - intensity flat field image,
 - badpixel-map,
 - ncomb-map,
 - rms-map;
- 4. zpl exp phase PI even sub-frame:
 - intensity flat field image,

Title: SPHERE Data Reduction Pipeline Manual REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 123/220

- badpixel-map,
- \bullet ncomb-map,
- rms-map.

Another products of the recipe are saved for both cameras in the MASTER FRAME format after combination of the resulting quad image into the final master frame products. This can be done either by simple averaging of the four sub-frames of the quad image or by using weighted mean formula where rms-map (calculated from error propagation) is taking into account to produce needed weights. These master intensity flat field calibration products (in the format of the MASTER FRAME) for both cameras are usually used in all subsequent polarimetric recipes that need to remove the pixel to pixel variation in the signal response of the detector. However, the quad image intensity flat field (in the format of the QUAD IMAGE, considered for monitoring purposes), may also feed the subsequent polarimetric recipes. The second linear fitting flat fielding procedure> descibed below (identical to that for the IFS and IRDIS) is then applied to the each zpl exp polarimetric sub-frames (zero odd, zero even, pi odd, pi even) seperately.

- 1. The mean value is determined for the respective sub-frame for all exposures.
- 2. For every pixel p = (x, y), a set of $m_i, v_i(x, y)$ data pairs are stored with m_i being the exposure mean value and $v_i(x, y)$ being the pixel value for exposure i.
- 3. The flat field value is defined as the slope c_i of a linear fit F to the data m_i, v_i .
- 4. The fit itself is performed either using a maximum likelyhood method or a robust fitting method which minimizes the sum of the absolute value of the deviations rather than the sum of the squares of the deviations (see e.g. Numerical Recipes for the algorithm). The robust fitting method will yield better results when significant outliers (e.g. due to cosmic rays) can be expected.
- 5. The flat field values (linear coefficients) are saved as an image as the main product of the recipe in the same QUAD IMAGE format (see above).

Aditionally, the recipe may also produce a separate output of all pixels that are identified as non-linear. The criteria for non-linearity are set by the user parameters and can be either pixels that have a flat field value outside specified bounds and/or pixels for which the linear fit produces a reduced chi-squared above a given threshold value. For reliable non-linearity flagging using the reduced chi-squared it is necessary to use many high quality input exposures. Since the badpixel treatment is somewhat complicated, some important points: the badpixels that are stored in the master flat field itself as produced by this recipe contain all the badpixels (for each sub-frames individually) at this point in the cascade. Pixels that were marked as bad from the input static badpixel map are also marked as bad here. The optional static badpixel output that is produced contains strictly only those pixel that the flat field recipe itself deemed to be bad. This does not necessarily include all the badpixels from the static badpixel input file.

3.4.2.6.5 Description:

The recipe creates master modulation/demodulation(modem) efficiency calibration product, using the input exposures which should be taken as described in the calibration plan. The input frames might be either modem efficiency raw frames with the ZPL MODEM EFF RAW pre-processed efficiency modemframes, which should ZPL MODEM EFF PREPROC CAM1 and/or ZPL MODEM EFF PREPROC CAM2 tags, and master bias calibration frames (if any) with the ZPL MASTER BIAS CAM1 and/or ZPL MASTER BIAS CAM2 tags, and master dark calibration frames (if any) with the ZPL MASTER DARK CAM1 and/or ZPL MASTER DARK CAM2 tags, and master intensity flat field calibration frames with the ZPL INT FLAT FIELD MASTER CAM1 ZPL INT FLAT FIELD MASTER CAM2 and/or tags, and polariztion field calibration frames with the ZPL POL FLAT PREPROC CAM1 and/or ZPL POL FLAT PREPROC CAM2 tags. The intensity flat calibration frames can be also used in the format of the QUAD IMAGE (see the description in sph zpl intensity flat recipe) with the corresponding ZPL INT FLAT FIELD CAM1 and/or ZPL INT FLAT FIELD CAM2 tags. If both formats of the intensity flat field calibrations are presented in sof-file the MASTER format will be used. If input frames are raw frames then the recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc for the detailed description of the pre-processing step). Then all pre-processed modem frames are organized in the two groups distinguished from each other by the opposite sign of the Stokes parameter [Qplus, Qminus]. The frames from each group are combined using the specified collapse algorithm (usually the clean mean algorithm, defined as a default one) for each zpl exposure sub-frames. The combined frame is of the QUAD IMAGE (16 extensions) format specified as follows: - zpl exp phase zero odd sub-frame combined image, badpixel-map, ncomb-map and rms-map; - zpl exp phase zero even sub-frame combined image, badpixel-map, ncomb-map and rms-map; - zpl exp phase PI odd sub-frame master combined image, badpixel-map, ncomb-map and rms-map; - zpl exp phase PI even sub-frame master combined image, badpixel-map, ncomb-map and rms-map. The master bias, dark and intensity flat field are applied to the two [Qplus, Qminus] combined master frames and then the Stokes parameters (I,P) are calculated for both frames and both cameras in the form of DOUBLE IMAGE: - master intensity Stokes parameter image, badpixel-map, ncomb-map and rms-map; -

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 132/220

master polarization Stokes parameter image, badpixel-map, ncomb-map and rms-map. Then, the polarization flat field is applied to the [Qplus, Qminus] Stokes parameters double image frames. This intermediate modem efficiency products for +Q and +Q are saved in the separate files (quality check). Finally, the two opposite polarization frames are combined by subtracting the MINUS polarization image frame from the PLUS one. The output modem polarization efficiency frames for both camera are calculated by dividing the polarization image by the intensity image (P/I). The final modem products are thus of the MASTER FRAME format specified as follows: modem efficiency image, badpixel-map, ncomb-map and rms-map. Note: if rawdata consist only of Qplus-data (or only Qminus-data) then the final products will be created directly from Qplus (or Qminus) double image (P/I). The final modem efficiency products for both cameras are used in all subsequent polarization recipes.

3.4.2.6.6 Products:

Name	Туре	Description
ZPL MODEM EFF	FITS[Im(4)]	The final modem efficiency frame is of
	/ / 3	the MASTER FRAME format. This
		frame contains 4 image extensions:
		modem efficiency image, badpixel-map,
		ncomb-map and rms-map.
ZPL MODEM	FITS[Im(4)]	The final modem efficiency frame is of
EFF CAM1		the MASTER FRAME format. This
_		frame contains 4 image extensions:
		modem efficiency image, badpixel-map,
		ncomb-map and rms-map.
ZPL_ MODEM_	FITS[Im(8)]	The resulting +Q modem efficiency
EFF_ QPLUS		frame is of the DOUBLE IMAGE
		format. This frame contains 8 image
		extensions: modem efficiency qplus
		intensity image, badpixel-map,
		ncomb-map and rms-map. modem
		efficiency qplus polarization image,
		badpixel-map, ncomb-map and
		rms-map.
ZPL_ MODEM_	FITS[Im(8)]	The resulting +Q modem efficiency
EFF_ QPLUS_ CAM1		frame is of the DOUBLE IMAGE
		format. This frame contains 8 image
		extensions: modem efficiency qplus
		intensity image, badpixel-map,
		ncomb-map and rms-map. modem
		efficiency qplus polarization image,
		badpixel-map, ncomb-map and
		rms-map.
ZPL_ MODEM_	FITS[Im(8)]	The resulting -Q modem efficiency frame
EFF_ QMINUS		is of the DOUBLE IMAGE format. This
		frame contains 8 image extensions:
		modem efficiency qminus intensity
		image, badpixel-map, ncomb-map and
		rms-map. modem efficiency qminus
		polarization image, badpixel-map,
		ncomb-map and rms-map.

zpl.star_ center_ cam2.outfilename	string	The output filename for the star center product, camera-2. Please also see the esorex documentation for naming of output products.	zpl_star_center_pol_cam2.fits	-
zpl.star_ center.subtract_ overscan	bool	Flag to set if the overscan mean values must be subtracted from pre-processed data (TRUE) Note that this parameter is applied if pre-processed data containt overscan table	1	-
zpl.star_ center.keep_ intermediate	bool	Flag to set if intermediate date must be saved, namely pre-processed and overscan pre-processed subtracted data (FALSE)	0	-
zpl.star_ center.save_ interprod	bool	Flag to set if the field center table must be saved as intermediate product (FALSE) Note that this parameter must be only applied for the offline pipeline	0	-
zpl.star_ center.coll_ alg	int	Set the collapse algorithm. The available algorithms: $0 = \text{Mean}, 1 = \text{Median}$. Default is $0 = \text{Mean}$.	0	0,1,2
zpl.star_ center.filter_ radius	double	Filter radius for frame combination. A non zero value leads to suppression of high frequencies in the fourier domain before frame combination. The value expresses the minimum unsuppressed frequency as fraction of total frequency domain radius (a value of 1 would suppress essentially all frequencies).	0.0	0.0-1.0
zpl.star_ center.sigma	double	The sigma threshold to use for source detections	10.0	-
zpl.star_ center.unsharp_ window	int	Before finding centres an unsharp algorithm is used on the image. This specifies the window width for the mask in pixels.	4	-
${\it zpl.preproc.outfilename_} \\ {\it cam1}$	string	The postfix- of the intermediate filename of the pre-processed raw data for the CAMERA-1.	preproc_ cam1.fits	-
zpl.preproc.outfilename_cam2	string	The postfix- of the intermediate filename of the pre-processed raw data for the CAMERA-2.	preproc_ cam2.fits	-

3.4.2.7.5 Description:

The recipe produces combined frame of the star center calibration measurements in

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 136/220

The input frames might be either science polarimetric raw the polarization modes. frames with the ZPL STAR CENTER POL RAW tag, or pre-processed science raw frames, which should carry the ZPL STAR CENTER POL PREPROC CAM1 and/or ZPL STAR CENTER POL PREPROC CAM2 tags, and calibration frames: ter bias calibration frames (if any) with the ZPL MASTER BIAS CAM1 and/or ZPL MASTER BIAS CAM2 tags, and - master dark calibration frames (if any) with the ZPL MASTER DARK CAM1 and/or ZPL MASTER DARK CAM2 tags, and - master intensity flat field calibration frames with the ZPL INT FLAT FIELD MASTER CAM1 ZPL INT FLAT FIELD MASTER CAM2 tags, and/or and frames with the ZPL POL FLAT PREPROC CAM1 calibration ZPL POL FLAT PREPROC CAM2 tags, and - modem/de-modulation (modem) efficiency calibration frames with the ZPL MODEM EFF CAM1 and/or ZPL MODEM EFF CAM1 The intensity flat calibration frames can be also used in the format of the QUAD IMAGE (see the description in sph_zpl_intensity_flat recipe) with the corresponding ZPL_INT_FLAT_FIELD_CAM1 and/or ZPL_INT_FLAT_FIELD_CAM2 tags. formats of the intensity flat field calibrations are presented in sof-file the MASTER format will be used. If input frames are raw frames then the recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc for the detailed description of the pre-processing step). The pre-processed frames are then calibrated by subtacting a corresponding master bias frame and a master dark frame, and dividing the results by a given intensity flat field frame. Then the Stokes parameters are calculated for each group creating double image (I,P) frames. The polarization flat and modem efficiency calibrations are applied to the created double image frames of the Stokes parameters. Then the calibrated frames are de-dithered (if needed) and saved as intermediate products (note: if the zpl.science pl.save interprod is set to TRUE, the recipe will also save the so called field center table which contains the the calculated center positions for each plane of the pre-processed fits cube(s)). All calibrated and de-dithered frames are avareged using collapse mean algorithm. The combined start center frames of the DOUBLE IMAGE (8 extensions) format specified as follows: - combined intensity image (I), its badpixel-map, ncomb-map and rms-map. - combined polarimetric image (P), its badpixel-map, ncomb-map and rms-map. The combined star center image is then analysed using an aperture detection algorithm: - The aperture detection algorithm detects all connected regions of at least 4 pixels size (area) that are the given sigma above the background. - The so detected waffle stars are then used to contruct a geometric centre of all stars found. This is then the frame centre. The recipe also works for the case that there is only one star (e.g. the coronograph is out and no waffle stars are formed). The coordinates of the detected frame centers are added as the keywords in the header of the output double images for each camera: - DRS ZPL STAR CENTER IFRAME XCOORD; - DRS ZPL STAR CENTER IFRAME YCOORD; - DRS ZPL STAR CENTER PFRAME XCOORD; - DRS ZPL STAR CENTER PFRAME YCOORD. This star center calibrated products for each camera should be used in the science polarimetric recipes.

might be either science polarimetric raw frames with the ZPL SCIENCE P1 RAW tag, or preprocessed science raw frames, which should carry the ZPL SCIENCE P1 PREPROC CAM1 and/or ZPL_SCIENCE_P1_PREPROC_CAM2 tags, and calibration frames: ter bias calibration frames (if any) with the ZPL MASTER BIAS CAM1 and/or ZPL MASTER BIAS CAM2 tags, and - master dark calibration frames (if any) with the ZPL MASTER DARK CAM1 and/or ZPL MASTER DARK CAM2 tags, and - master intensity flat field calibration frames with the ZPL INT FLAT FIELD MASTER CAM1 ZPL INT FLAT FIELD MASTER CAM2 tags, and polariztion ZPL POL FLAT PREPROC CAM1 calibration frames with the ZPL POL FLAT PREPROC CAM2 tags, and - modem/de-modulation (modem) efficiency calibration frames with the ZPL MODEM EFF CAM1 and/or ZPL MODEM EFF CAM1 The intensity flat calibration frames can be also used in the format of the QUAD IMAGE (see the description in sph zpl intensity flat recipe) with the corresponding ZPL_INT_FLAT_FIELD_CAM1 and/or ZPL_INT_FLAT_FIELD_CAM2 tags. formats of the intensity flat field calibrations are presented in sof-file the MASTER format will be used. If input frames are raw frames then the recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc for the detailed description of the pre-processing step). Then, all pre-processed raw science frames are organized in the measurement groups with regards to the Stokes parameters: Q [Qplus, Qminus] and/or or U [Uplus, Uminus]. These input frames frames should carry the SPH_ZPL_TAG_SCIENCE P1 PREPROC RAW tag. The pre-processed frames of each group for both cameras are then calibrated by subtacting a corresponding master bias frame and a master dark frame, and dividing the results by a corresponding intensity flat field frame. Then the Stokes parameters are calulated for each group creating double image (I,P) frames. The polarization flat and modem efficiency calibrations are applied to the created double image frames of the Stokes parameters. The calibrated frames of each group are then de-dithered, de-rotated and saved as intermediate products (note: if the zpl.science p1.save interprod is set to TRUE, the recipe will also save the so called field center table which contains the the calculated center positions and parallactical angles (to be more specific: an angle to be used for the de-rotation) for each plane of the pre-processed fits cube(s)). Note: the calibration frames with SPH ZPL TAG STAR CENTER POL CALIB CAM1(CAM2) tags provide the center coordinates to rotate around. If these calibrations are not presented the center of the frames will be used (normally, xc=yc=512 pixel). All de-dithered and de-rotated frames are avareged using collapse mean algorithm (for each group Qplus, Qminus, Uplus, Uminus). The combined frames of each groups of the DOUBLE IMAGE (8 extensions) format specified as follows: - combined intensity image (I), its badpixel-map, ncomb-map and rms-map. - combined polarimetric image (P), its badpixel-map, ncomb-map and rms-map. At the final step the double image frames (Qplus and Qminus) as well as (Uplus and Uminus) are combined polarimetrically (Q: I = [I(+Q) + I(-Q)]/2, P = [P(+Q) - P(-Q)]/2; U: I = [I(+U) + I(-U)]/2, P = [P(+U) + I(-U)]/2,P(-U)]/2) The output Q and/or U double images for both cameras are reduced pipeline data products.

3.4.2.9.3 Raw frame keywords used:

Keyword	Type	Optional	Description
ESO DRS PC PROD TYPE	string	No	This keyword is mandatory if the pre-processed data are
			used. As the format of the zimpol pre-processed data is
			complicated, this keyword was introduced in order to
			garantee that the pre-processed input frames are
			polarimetric pre-processed data, produced by the
			sph_zpl_preproc utility recipe. Note: if raw data are
			used (default), then all keywords needed for the
			pre-processing recipe (see sph_zpl_preproc) must be
			presented in the raw data.
ESO OCS3 ZIMPOL POL STOKES	string	No	Stokes parameters (Qplus, Qminus, Uplus, Uminus)
			SPH_COMMON_KEYWORD_CAM1_DITHERING_X
			double 0 0 100.0 X-position of the arm1(camera-1) [pix]
			SPH_COMMON_KEYWORD_CAM1_DITHERING_Y
			double 0 0 100.0 Y-position of the arm1(camera-1) [pix]
			SPH_COMMON_KEYWORD_CAM2_DITHERING_X
			double 0 0 100.0 X-position of the arm2(camera-2) [pix]

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 151/220

3.4.2.9.5 Description:

The recipe produces combined science frame [and corresponing Mueller matrix elements (not implemented)] of the Q and/or U measurements the in the polarization modes. The input frames might be either science polarimetric raw frames with the ZPL SCIENCE P23 RAW tag, or preprocessed science raw frames, which should carry the ZPL SCIENCE P23 PREPROC CAM1 and/or ZPL SCIENCE P23 PREPROC CAM2 tags, and calibration frames: ter bias calibration frames (if any) with the ZPL MASTER BIAS CAM1 and/or ZPL MASTER BIAS CAM2 tags, and - master dark calibration frames (if any) with the ZPL MASTER DARK CAM1 and/or ZPL MASTER DARK CAM2 tags, and - master intensity flat field calibration frames with the ZPL INT FLAT FIELD MASTER CAM1 ZPL INT FLAT FIELD MASTER CAM2 and/or tags, and - polariztion ZPL POL FLAT PREPROC CAM1 frames field calibration $_{
m with}$ $_{
m the}$ ZPL POL FLAT PREPROC_CAM2 tags, and - modem/de-modulation (modem) efficiency calibration frames with the ZPL_MODEM_EFF_CAM1 and/or ZPL_MODEM_EFF_CAM1 tags. The intensity flat calibration frames can be also used in the format of the QUAD IMAGE (see the description in sph_zpl_intensity_flat recipe) with the corresponding ZPL INT FLAT FIELD CAM1 and/or ZPL INT FLAT FIELD CAM2 tags. If both formats of the intensity flat field calibrations are presented in sof-file the MASTER format will be used. If input frames are raw frames then the polarization flat recipe first performs the pre-processing step for all input frames (raw cubes), creating corresponding pre-processed frames (cubes) for both ZIMPOL cameras (see also sph zpl preproc for the detailed description of the pre-processing step). Then, all pre-processed raw science frames are organized in the measurement groups with regards to the Stokes parameters: Q [Qplus, Qminus] and/or or U [Uplus, Uminus]. These input frames frames should carry the SPH ZPL TAG SCIENCE P23 PREPROC RAW tag. The pre-processed frames of each group for both cameras are then calibrated by subtacting a corresponding master bias frame and a master dark frame, and dividing the results by a corresponding intensity flat field frame. Then the Stokes parameters are calculated for each group creating double image (I,P) frames. The polarization flat and modem efficiency calibrations are applied to the created double image frames of the Stokes parameters. The calibrated frames of each group are then de-dithered, de-rotated and saved as intermediate products (note: if the zpl.science p23.save interprod is set to the 1, the recipe will also save the so called field center table which contains the the calculated center positions for each plane of the pre-processed fits cube(s)). All de-dithered frames are avareged using collapse mean algorithm (for each group Qplus, Qminus, Uplus, Uminus). The combined frames of each groups of the DOUBLE IMAGE (8 extensions) format specified as follows: - combined intensity image (I), its badpixel-map, ncomb-map and rms-map. - combined polarimetric image (P), its badpixel-map, ncomb-map and rms-map. At the final step the double image frames (Qplus and Qminus) as well as (Uplus and Uminus) are combined polarimetrically (Q: I = [I(+Q) + I(-Q)]/2, P = [P(+Q) - P(-Q)]/2; U: I = [I(+U) + I(-U)]/2, P = [P(+U) + I(-U)]/2,P(-U)]/2) The output Q and/or U double images for both cameras are reduced pipeline data products.

Chapter 4

Instrument Data Description

In this section we describe the raw data, including the for DRH relevantDPR keywords for each data type. All valid combinations of FITS DPR keywords are identified, listed and identified with corresponding recipes which need to use them as input.

For each of these data structures the basic data type is a FITS file withan image in the HDU corresponding to the full 2048x2048 pixel region of the detector and no extensions. The keywords in the header of the FITS file depend strongly on the datastructure represented. The following table lists the keywords for each of the data structures for technical, science and monitoring calibrations.

General Data Layout A raw SPHERE file always has the images stored in the primary FITS dataunit. Please see the FDR document for a table that lists the raw data types, the corresponding calibrations (names as in the calibration plan) etc. In sections 9-11 of this manual the data types, keywords etc are listed for each recipe.

Imaging Frames The raw imaging frames for IFS and IRDIS all contain in total 2048x2048pixels. For IRDIS all raw frames that are obtained with calibrations that illuminate the detector through the IRDIS optical path, only an area of 2048x1024pixels is used. This again is split in two parts for classical imaging and DBI modes.

Image Coordinate System In several places the SPHERE recipes report coordinates, in particular of a reported frame center, determined star position, or similar. These positions are communicated to the user by the means of header keywordsor dedicated product files, either as FITS tables or, optionally, simplyascii output. When comparing these coordinates to values derived by the means of using other tools, care should be taken about the coordinate system in use. Many ways exist to describe locations in image frames, and while the SPHERE pipeline uses pixel coordinates, there are also different ways of defining the pixel grid coordinate system. The FITS standard has its own definition, and the various FITS viewing tools and scripting (and other programming) languages follow different standards.

Coordinates reported (or used as input) by the SPHERE pipeline always refer to the following scheme: For an image consisting of NxM pixels, the coordinate (0,0) refers to the lower left corner of the lower left pixel. The coordinate (N,M) refers to the upper right corner of the upper right-pixel. The midpoint of the lower left pixel has the coordinate (0.5,0.5), and the image midpoint (N/2,M/2).

calibdata/zimpol:

4.2.1 IFS lenslet model

Several recipes, in particular the wavelength calibration, spectra positions and IFU flat recipes require a model of the lenslet. This model describes how the lenslets are projected onto the detector in some standard dithering position (the "zero"position). In future version this may be extended to include other relevant IFS in strumentmodel parameters, like filter parameters, etc. In the current version, the lenslet model can be provided either as header information in a FITS file or more easily as a simple ASCII text file which is written in the "ini"style format of "KEY = VALUE" pairs on each line.

4.2.1.1 Parameters of the IFS lenslet model

The IFS default lenslet model is given by the following parameters and values:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 160/220

The IFS lenslet model may be given using a seperate ASCII file. The standard default model for the J mode would be given in the followingway:

```
[ ESO DRS IFS LENSLET MODEL ]
ESO DRS IFS DET PIX SIZE = 2048
ESO DRS IFS LENS N SIDE = 145
ESO DRS IFS PIX SIZE = 18.000000
ESO DRS IFS LENS SIZE = 161.500000
ESO DRS IFS SPEC PIX LEN = 39.000000
ESO DRS IFS SPEC PIX WIDTH = 4.930000
ESO DRS IFS ROTANGLE = -11.000000
ESO DRS IFS BIGRE SCALE = 0.000045957
ESO DRS IFS BIGRE ROT OFF = -8.769100
ESO DRS IFS OFF X = 2.000000
ESO DRS IFS OFF Y = 8.000000
ESO DRS IFS SCALE X = 1.000000
ESO DRS IFS SCALE Y = 1.000000
ESO DRS IFS MAX LAMBDA = 1.346000
ESO DRS IFS MIN LAMBDA = 0.950000
```

The meaning for the various parameters relating to the spectra (spectralength, minimum and maximum wavelength) are illustrated in Fig.4.1.A cross section of a typical spectrum with a broad band lamp is shown at the top of the figure.Below, the diagram illustrates the meaning of the principal parameters and how the spectrum extraction works. The grey area marks the area as predicted from the lenslet model above, a box with the width and length as specified by the ESO DRS IFS SPEC PIX LEN and ESO DRS IFS SPEC PIX WIDTH parameters. The exact position of the spectrum on the detector is determined by the hexagonal arrangement of the BIGRE lenslet array and the ESO DRS IFS ROTANGLE, ESO DRS IFS ROT OFF, ESO DRS IFS OFF X, ESO DRS IFS OFF Y and ESO DRS IFS parameters are fitted for in the spectra positions recipe.

When extracting the spectra, only those pixels are extracted that fall fully inside the predicted spectra model region (the blue area in the diagram). Note that this means that, e.g.for a model spectra length of 39 pixels, the extracted region will always only be 38 pixels long. The minimum and maximum wavelength then refer to the midpoints of the first and last pixels in this model region. The minimum and maximum wavelengths of the model are "guidance" values only: the wavelength calibration recipe for IFS will determine the actual minimum and maximum wavelengths of each spectra region. The dispersion is calculated on the model spectrum and is $\Delta\lambda = (\lambda_{max} - \lambda_{min}) / (L_{model} - 2), \text{where } L_{model} \text{ is the model length of the spectra.} \text{As seen from the diagram, the length of the extracted spectra } L_{extract} = L_{model} - 1 \text{if } L_{model} \text{is an integer value.} \text{In that case, the dispersion is: } \Delta\lambda = (\lambda_{max} - \lambda_{min}) / (L_{extract} - 1).}$

4.2.2 IRDIS Instrument model

Similarly as for IFS, several recipes for IRDIS also rely on an "instrument model". The IRDIS instrument model is much simpler and currently only contains information on the detector regions corresponding to the different optical paths (left and right paths). It is automatically created in the instrument flat recipe and the model information is stored in the header of the master instrument flat field. It is usually not needed to change this information. The model is valid for the "zero" dithering position. In future version the model may be extended to include other relevant IRDIS instrument model parameters, like filter parameters, etc. In the current version, the lens let model can be provided most easily as a simple ASCII text file which is written in the "ini" style format of "KEY = VALUE" pairs on each line.

4.3 Data Reduction Pipeline Data Products Format

4.3.1 Calibration Products Data Representation

For both IRDIS and IFS, the data reduction pipeline creates calibration products in a variety of formats. The two most general formats are described in this section, but see the description of the individual recipes for more detailed information and information on other data product formats.

4.3.1.1 The SPHERE "master frame"

The most simple data product produced by the SPHERE pipeline consists of a FITS file with 4 extensions, all containing a single plane (NAXIS = 2) and all having the same number of pixels in both x and y (for IFS and IRDIS this will be NAXIS1 = NAXIS2 = 2048 in most cases). The extensions have the following meaning:

Extension Number	Type	BITPIX	Meaning
1	FLOAT	-32	Image / Main values
2	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$
			= bad $)$
3	FLOAT	-32	Weightmap (e.g.number of
			pixels that went into result)
4	FLOAT	-32	RMS Error / Other Error Info

4.3.1.2 Seeing double: The SPHERE double image

For all instruments several calibration (and also raw data) consist of two associated images. This is specifically true for IRDIS, which uses a double optical path close to the detector, and ZIM-POL which stores two interlaced separate images one readout detector frame using pixel-shifting. Also for IFS some information, like the distortion vector of the lensletarray has an inherit two-component data structure. In nearly all such cases the SPHERE pipelines uses the same data format: a FITS file which consists of a total of 8 extensions. These 8 extensions are:

Extension Number	Type	BITPIX	Meaning	
1	FLOAT	-32	Image / Main values for	
			"A"image	
2	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$	
			= bad) for "A" image	
3	FLOAT	-32	Weightmap (e.g.number of	
			pixels that went into result) for	
			"A"image	
4	FLOAT	-32	RMS Error / Other Error Info	
			for "A"image	
5	FLOAT	-32	Image / Main values for	
			"B"image	
6	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$	
			= bad $)$ for "B" image	
7	FLOAT	-32	Weightmap (e.g.number of	
			pixels that went into result) for	
			"B"image	
8	FLOAT	-32	RMS Error / Other Error Info	
			for "B"image	

In this table, the data represented by the "A" and "B" image depend on the specific instrument and

Page: 163/220

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58 Date: 2025-06-11

recipe: for example, for the sph_ird_science_dpi recipe, the "A"image represents the intensity image, I, and image "B" the polarisation, P.

4.3.1.3 The SPHERE quad image

Some of ZIMPOL instrument calibration output product consists of 4 associated images. This is the consequence of the fact that one zimpol exposure contains two interlaced images for both phases (0 and PI). Thus, a save quad image FITS file consist of a total of 16 extensions. The 16 extensions are:

Extension Number	Type	BITPIX	Meaning
1	FLOAT	-32	Image / Main values for
			"A"image (phase 0)
2	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$
			= bad) for "A" image (phase 0)
3	FLOAT	-32	Weightmap (e.g.number of
			pixels that went into result) for
			"A"image
4	FLOAT	-32	RMS Error / Other Error Info
			for "A"image (phase 0)
5	FLOAT	-32	Image / Main values for
			"B"image (phase 0)
6	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$
			= bad) for "B" image (phase PI)
7	FLOAT	-32	Weightmap (e.g.number of
			pixels that went into result) for
			"B"image(phase 0)
8	FLOAT	-32	RMS Error / Other Error Info
			for "B"image (phase 0)
9	FLOAT	-32	Image / Main values for
			"A"image (phase PI)
10	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$
			= bad $)$ for "A" image (phase PI)
11	FLOAT	-32	Weightmap (e.g.number of
			pixels that went into result) for
			"A"image (phase PI)
12	FLOAT	-32	RMS Error / Other Error Info
			for "A"image ((phase PI)
13	FLOAT	-32	Image / Main values for
			"B"image (phase PI)
14	SHORT	8	Bad or flagged pixels $(0 = ok, 1)$
			= bad $)$ for "B" image
15	FLOAT	-32	Weightmap (e.g.number of
			pixels that went into result) for
			"B"image(phase PI)
16	FLOAT	-32	RMS Error / Other Error Info
			for "B"image (phase PI)

The quad image format is currently used for the new version of the ZIMPOLmaster bias and master dark.

Chapter 5

Mathematical Description

Here we describe the mathematical algorithms that are used for data reduction. In addition, this chapter serves as an overview of the general data reduction process.

5.1 Signal propagation through DRH

For a scientific exposure, the most general observation mode for SPHERE, the scientific signal as given by an input flux $S(\alpha, \beta, \lambda)$ results in a detector image, I(x, y)that represents the electrons received by the detector and converted into counts including all instrumental effects. Here the physical (or "sky") coordinates α, β are transformed onto the detector pixels x, ythrough the dispersive elements, with the mapping

$$S(x,y) = S(x_{\Delta x, \Delta y}(\alpha, \beta, \lambda), y_{\Delta x, \Delta y}(\alpha, \beta, \lambda)),$$

with the pixel to lenslet associations $x_{\Delta x,\Delta y}(\alpha,\beta,\lambda)$ and $y_{\Delta x,\Delta y}(\alpha,\beta,\lambda)$. These pixel to lenslet associations depend on the relative offset betweenlenslet array and detector, Δx and Δy and are determined during the wavelength calibration procedures. We will henceforth write $S(x,y;\lambda)$ for $S(x_{\Delta x,\Delta y}(\alpha,\beta,\lambda),y_{\Delta x,\Delta y}(\alpha,\beta,\lambda))$, representing the pixelised science image, i.e.a 2-D detector image of the lenslet array that is devoid of instrumental effects. We write the λ dependence here as a reminder that this is a 2D representation of a wavelength cube.

From the entrance into the telescope the scientific signal is affected by several components in an adverse manner, and all these effects have to be removed by the data reduction process in order to achieve maximal scientific output. This is achieved by applying several transformation to the detected image, I(x,y) to reverse the actions of the instrumental and telescope effects. These transformations are in general applied in a sequential manner, reflecting the physical layout of the detecting system, which consists of several components each of which affects the input signal in series. However, it is important to keep this assumption of "sequentially" which underlies most of the principles of astronomical data reduction inmind. In order to allow the removal of the various effects by the instrument/telescope components, one attempts to isolate and measure the effect of each individual component in a calibration procedure which is executed in a separate stepto the science observation, either at various times during the observation inght, during the preceding day or only at specific times throughout theyear.

The data reduction handling for the IFS subsystem of SPHERE provides calibration procedures to measure and correct for the most important instrumental effects. Realizing that the IFS system can essentially be broken down into three relevant parts: the detector including readout electronics, the instrument, including optical components like lenslets and the telescope, including the SPHERE "common path", the signal propagation can be represented by a series of components that act on

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 165/220

Figure 5.1: Schematic representation of the hardware components for IFS from a DRH point of view. The signal is affected by various hardware components which are calibrated out on the data reduction process. For each component the basic mathematical effect is given either as addition, division or multiplication. The first left most effects are all included in the "science" signal $S(x, y; \lambda)$ below.

the input signal $S(x, y; \lambda)$. We show these components schematically in Fig 3.1.Mathematically the signal propagation can be represented with the following equation:

$$I(x,y) = G \times \{DC(x,y) \times \Delta t + B(x,y) + DF(x,y,\lambda) \times IF(x,y,\Delta x,\Delta y,\lambda) \times S(x,y;\lambda)\} + RON,$$
(5.1)

where G is the total gain, DC the dark current, B the bias, DF the detectorflat response, IF the instrument flat response, RON the readout noise, Δx the detector dither offset in x, Δy the detector offset in y. The exposure time, Δt has the special property (due to the detector technology) that

$$\Delta t = n \times T, \ n > 1,$$

where T is a constant exposure time unit, around 1.3sec.Note that $n \ge 1$ and so an exposure time of $\Delta t = 0$ is not possible. This also means that a "bias", defined as the detector response for zero exposure time, can not be measured directly for IFS and IRDIS but has to be inferred.

All the functions for the system components, DC, B, DF, IF and TF are writtenin detector pixel coordinates, even if the corresponding calibrations maybe detector position independent. For example, the instrument flat field is the effect of the lenslet arrayon the signal, which is a function of lenslet and wavelength but is independent to the detector position. The signal as received in detector pixel coordinates, however, is dependent to the detector offset simply due to a shift in coordinate system. In this sense the functions for the system components defined in the equationabove rather represent the detected signal on the detector if all othercontributions are zero. The response functions of the detector, the instrument and the telescopeare assumed to be linear in the signal S. Linearity of these components, for signals in unsaturated regimes, is part of the SPHERE hardware requirement specification and the linearity assumption therefore in general justified. An exception are image ghosts (due to optical reflections) and persistence effects.

5.2 Signal propagation reversal

Given the above signal response equation, the inverse can be formulated to infer the original science signal from the detected image:

$$S(x,y;\lambda) = \frac{\left[I(x,y) - RON\right]/G - DC(x,y) \times \Delta t - B(x,y)}{DF(x,y,\lambda) \times IF(x,y,\Delta x, \Delta y, \lambda) \times TF(x,y,\Delta x, \Delta y, \lambda)}.$$

The statistical mean of the readout noise should be zero (by choice), simplifying the equation slightly to:

$$S(x,y;\lambda) = \frac{I(x,y)/G - DC(x,y) \times \Delta t - B(x,y)}{DF(x,y,\lambda) \times IF(x,y,\Delta x,\Delta y,\lambda) \times TF(x,y,\Delta x,\Delta y,\lambda)}.$$
 (5.2)

Knowledge of the functions DC, B, DF, IF and TF and the gain allows onether to determine the scientific signal from the observed detector image. The various functions are determined in the calibration procedures by isolatingthe relevant components, using a known input source signal S and processing the detector image.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 166/220

5.3 Signal propagation for bias and dark calibrations

The signal propagation for bias and dark calibration is very simple sincethe signal S is zero:

$$I(x,y) = G \times [DC(x,y) \times \Delta t + B(x,y)] + RON.$$

Assuming that the statistical mean of the readout noise is zero, the biasand dark term can simply be obtained as

$$DC(x, y) \times \Delta t + B(x, y) = I(x, y)/G.$$

Thus, taking an exposure with closed shutters and dividing by the gain, directly gives the dark+bias contribution. However, note that this depends on the exposure time. Also, since conversion from electrons to counts in the detector also depends on the readout mode, a bias+dark measurement is required for each exposure time and readout mode used in any observation which is to be processed. This is generally true for all detector effects and will be neglected in the further treatment in this chapter (the only consequence is that every measurement is performed for each possible combination of exposure time and readout mode). In the case that a separate measurement of the components DC and B is required, the following description can be used: repeatedly expose the detector for different times Δt thereby obtaining $I(x,y,\Delta t)$ and perform a linear fit to the observed count, $I(x,y,\Delta t)=k(x,y)\times\Delta t+b(x,y)$. Comparison with the above equation directly yields the dark and bias components. Note that this procedure is necessary because an exposure time of 0s is not possible for the infrared detector and so the bias can not be measured using 0s exposures as for optical CCDs.

5.3.1 A special note about the dark calibration and the use of the word "dark"in this document

Even though the calibration plan foresees a master "dark" calibration, and the calibration as well as the result is referred to as "dark calibration" and "dark" or "master dark" throughout this document, this is not really the correct terminology that should be used for this recipe in the case of IRDIS and IFS. Since the dark current is very low for IR detectors, both IRDIS and IFS, what is actually calibrated in this recipe is the so called "Fixed Pattern Noise", or FPN, which represents the spatial variation of the response of pixels a zero input stimulus. This is dependent on integration time as well as read out mode and may vary on relatively short timescales. To keep with the terminology of the calibration plan we shall continue to refer to this calibration as the "dark" calibration also for the infrared detectors of IFS and IRDIS.

5.4 Signal propagation for the detector flat field

In this case, the detector is illuminated with a uniform lamp of a givenwavelength, giving a signal $S(x, y; \lambda) = L(\lambda)$ that is uniform over the detector and depends only on the wavelength, or, more generally, on the spectral energy distribution of the lamp used. Since neither the instrument components (lenslet arrays) or the telescope are involved the detected image is given by:

$$I(x,y) = G \times \{DC(x,y) \times \Delta t + B(x,y) + DF(x,y,\lambda) \times L(\lambda)\} + RON.$$

Knowledge of the bias and dark component from previous measurements, and exploiting the statistical mean of the readout noise of zero gives:

$$DF(x, y, \lambda) = \frac{I(x, y, \lambda)/G - DC(x, y) \times \Delta t - B(x, y)}{L(\lambda)}.$$

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 167/220

This means that the detector flat field response for a given wavelength is measured by taking an exposure of time Δt and subtracting a bias+dark calibration frame with the same exposure time. In general the lamps used for calibration purposes are not perfectly monochromatic, and some detector flats are even taken with a white lamp, giving:

$$DF_L(x,y) = \int \left[(I(x,y,\lambda)/G - DC(x,y) \times \Delta t - B(x,y))/L(\lambda) \right] d\lambda,$$

where $L(\lambda)$ is the normalized wavelength emission of the calibration lamp L used. Since the actual quantity required in equation 5.2 is $DF(x,y,\lambda)$, it is necessary to extrapolate from a series of $DF_L(x,y)$ for different calibration lamps, L=1...N. In practice, the calibration lamps used for SPHERE have a small bandwidthand can be assumed to be monochromatic (except for the broad band lamp), giving directly $DF(x,y,\lambda_L)$. Since only a finite number of such calibration lamps are available, it is not possible to determine $DF(x,y,\lambda)$ for every wavelength directly. Rather, determination of $DF_L(x,y)$ for all monochromatic calibration lamps can be used to construct a fitfunction for every pixel, $f_{x,y}(\lambda)$ which in turn can be used to construct an estimate of $DF(x,y,\lambda)$ for every wavelength. The accuracy of this then depends on the number of monochromatic calibration lamps used, and how well the wavelength dependence of the pixel response a be described by the fitting function chosen.

5.5 Signal propagation for the instrument flat field

5.5.1 Instrument flat field for IFS

For the instrument flat field for the IFS, the set-up is similar to the detector flat field, except that the lenslet array and some related optical components are in the light path. The equation for the signal propagation, eq.5.1 becomes:

$$I(x,y) = G \times \{DC(x,y) \times \Delta t + B(x,y) + DF(x,y,\lambda) \times IF(x,y,\Delta x,\Delta y,\lambda) \times L(\lambda)\},\$$

where $L(\lambda)$ is the spectral energy distribution of the calibration lamp and we have assumed that the mean of the readout noise is zero. Now, the calibration measurement is the same as that for the detector flat field, except that we now measure the product $DF(x,y,\lambda) \times IF(x,y,\Delta x,\Delta y,\lambda)$ instead of just $DF(x,y,\lambda)$. Since no lenslet array is used in the detector flat exposure, detector flats are independent of the detector position. However, the pixel associated is detector position dependent, and so, in order to measure $IF(x,y,\lambda)$ the pixel positions have to be remapped through the pixel description table before a detector flat is divided out. The main purpose of the sph_ifs_instrument_flat recipe described later is to create a calibration frame which contains only the $IF(x,y,\lambda)$ part and is detector position in dependent. These IFU flat calibration frames can simply be obtained in any detector position as long as detector flat fields taken at the same detector position are divided out. Again the limited availability of calibration lamps means that the wavelength dependence will be estimated by functional fits, $f_{x,y}(\lambda)$, to a series of measurements at the different calibration wavelengths, such that

$$DF(x, y, \lambda) \times IF(x, y, \Delta x, \Delta y, \lambda) = f_{x, y, \Delta x, \Delta y}(\lambda).$$
 (5.3)

Recipes that need to correct for the instrument flat field use a set of master input detector flat fields in combination with the detector position independent master IFU flat field to construct the function $f_{x,y,\Delta x,\Delta y}(\lambda)$. Which fitting function to use is decided within the recipe and may be a parameter to the recipe plugin. We should note here, that the λ dependence of the lenslet response is expected to be small – and it may in principle be possible to simplify the data reduction process in this case.

REF: VLT-TRE-SPH-14690-660/1/0

Date: 2025-06-11 Page: 168/220

For IFS the quantity on the left hand side of equation 5.3 multiplied by the wavelength association mask as obtained during the wavelength calibration (described further below)

$$SF(x,y) \equiv \int DF(x,y,\lambda) \times IF(x,y,\Delta x,\Delta y,\lambda) \times \delta(\lambda - \lambda_{x,y}) d\lambda$$
 (5.4)

Issue: 1 Version 58

is referred to as the "Super Flat". In the equation defining SF(x,y) $\delta(\lambda)$ is the Dirac delta function and $\lambda_{x,y}$ is the wavelength associated with the pixel at x,y through the wavelength calibration. This quantity is measured directly in the sph_ifs_instrument_flat recipe, but we reiterate that for reduction of IFS science frames it is not enough to measure the quantity SF(x,y) in one single calibration since the different quantities entering S(x,y) vary on different timescales. Therefore the super fat is reconstructed from separate master calibration files of DF, IF and the wavelength calibration within all science observation and calibration data reductions. Also note that SF(x,y) is dither position dependent.

5.5.2 Instrument flat for IRDIS

Fir IRDIS there is no detector flat field, and there exists only the instrumentflat field calibration. Also, since the main observing modes for IRDIS are imaging modes, the wavelength dependence is implicit only and the instrument flat field becomes

$$FF_{imaging}(x, y; F) \equiv \int DF(x, y, \lambda) \times IF(x, y, \Delta x, \Delta y, \lambda) \times F(\lambda) d\lambda,$$
 (5.5)

where the flat quantity $F(\lambda)$ is the filter transmission curve. For the DBI mode, the filter will be different for the left and right sub-windows of the detector. Again, note that for IRDIS, as opposed to IFS, the quantity DF and IF are not measured separately, but only FF(x, y; F) is measured. This also means that I is, strictly speaking, dithering dependent.

For the spectroscopy mode, the flat field is defined in an analogous wayto IFS as

$$FF_{spec}(x, y; F) \equiv \int DF(x, y, \lambda) \times IF(x, y, \Delta x, \Delta y, \lambda) \times F(\lambda) \times \delta(\lambda - \lambda_{x,y}) d\lambda.$$
 (5.6)

Again, the flat field is measured in its entirety. It is therefore both filter as well as dithering dependent.

5.6 Finding spectral regions in IFS

For the IFU capabilities of the IFS it is necessary to identify all theregions where spectra fall onto the detector in an automatic way. In principle this needs to be done for every possible detector positionin a separate calibration step implemented as the sph_ifs_spectra_positions in the data reduction library. However, the creation of detector position dependent PDTs is done purely in the data reduction recipes: only one "master" PDT table for the standard dithering position is created during calibrations. PDTs for other dithering position are calculated from the dithering position and this master PDT. The simplest algorithm for detecting spectral regions proceeds as follows:

- 1. Create dark subtracted master calibration frames from the input raw frames.Bad pixels must be flagged/set to zero.
- 2. Divide this frame by a master detector flat field taken with the broad band(white light) lamp.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 169/220

3. Apply a threshold algorithm to identify regions with pixel values above certain threshold value.

- 4. Assign a label for each connected region.
- 5. Associate these regions from the regions as expected from a model of thelenslet array. Regions that are either associated to two different lenslet IDs or that have no lenslet ID associated from model are counted and marked.
- 6. Save label information for each pixel in the pixel description table (PDT). Pixels outside spectral regions are given label 0.

The advantage of this procedure is that it is very simple and the spectralregions have been identified using a clear criterion. This procedure is also very robust to "missing" lenslets or gaps. However, this simple minded approach has the disadvantage of requiring a flat spectra response, that is, the signal along a spectrum must be highand the contrast with regions that do not contain spectra must be high. This is not always the case, since the detector is likely to have a stronglywavelength dependent sensitivity the spectra will not be flat on the detectorand in some regions the detector sensitivity may be so low that the contrastis not high enough. In addition this procedure does not take account of the fact that the boundaryof spectra do not fall exactly in between pixels; some pixels will be illumination partly by a spectrum, further reducing the contrast with un-illuminated regions. All this means that the performance of this procedure depends rather critically on the choice of the threshold parameter.

An alternative approach, used in the current SPHERE pipeline, uses a model function of the spectra locations to improve on the simple thresholding approach. This model can be provided simply as an image, M(x',y'), where

$$M(x', y') = \begin{cases} 0 & off \ spectra \\ 1 & on \ spectra \end{cases},$$

The determination of spectral regions on the observed detector image, I(x, y) then just becomes an optimization problem for finding the offset between $\Delta x = x' - x$ and $\Delta y = y' - y$ such that the difference in observed illuminated and predicted spectral regions is minimal and, ideally,

$$I(x + \Delta x, y + \Delta y) = M(x', y').$$

The model itself is derived from the IFS instrument model as described in 4.2.1. For all the details on the spectra positions procedure please see the recipedescription in ??.

5.7 The IFS wavelength cube and IFS wavelength calibrations

5.7.1 The wavelength cube

For science data reduction purposes of IFU data it is necessary to perform series of wavelength calibration procedures. Regions on the detector have to be identified where the spectra fall on and every pixel has to be corrected for the wavelength dependent effects. In general, any IFU data at spatial coordinates α , β and at wavelength λ will be constructed from a detector image I(x,y)(obtained with the lenslet array in the optical path) in the following way:

$$IFU(\alpha, \beta, \lambda) = I(x_{\Delta x, \Delta y}(\alpha, \beta, \lambda), y_{\Delta x, \Delta y}(\alpha, \beta, \lambda)),$$

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 170/220

with the pixel to lenslet associations $x_{\Delta x, \Delta y}(\alpha, \beta, \lambda)$ and $y_{\Delta x, \Delta y}(\alpha, \beta, \lambda)$. These pixel to lenslet associations depend on the relative offset betweenlenslet array and detector and are determined during the spectra positions procedures described in section 3.6.In order to associate the detector pixels with the correct wavelength, a known line spectrum is used to illuminate the detector. Spectral regions are identified and a fit is performed to determine the pixel coordinates of the known line centers of the spectrum. For every lenslet spectrum a table associating the line wavelengths with pixels information is constructed and a fitting/interpolation procedure is used to associate wavelengths for all pixels in between. In this way every pixel will be associated with a lenslet (i.e. α and β coordinates) and a wavelength. Since the procedure makes use of the same instrument set-up as used for the instrument flat procedures the resulting detector image is:

$$I_{\Delta x, \Delta y}(x, y) = G \times \{DC(x, y) \times \Delta t + B(x, y) + DF(x, y, \lambda) \times IF(x, y, \Delta x, \Delta y, \lambda) \times S(x, y; \lambda)\}.$$

However, contrary to the instrument flat field procedure we are not interested in obtaining $I(x, y, \lambda)$ but rather, we wish to obtain $S(x, y; \lambda)$, the "true" input signal, i.e.the idealized projection of the spectra after having gone through the lensletarray. Using the reversed propagation equation 5.2, we can write

$$S_{\Delta x, \Delta y}(x, y; \lambda) = \frac{I(x, y)/G - DC(x, y) \times \Delta t - B(x, y)}{DF(x, y, \lambda) \times IF(x, y, \Delta x, \Delta y, \lambda)}.$$

Thus, a reconstruction of $S(x, y; \lambda)$ can be achieved if the bias and dark current $DC(x, y)\Delta t + B(x, y)$ as well as the instrument flat $DF(x, y, \lambda) \times IF(x, y, \Delta x, \Delta y, \lambda)$ are measured accurately. When a white flat field lamp is used as the illumination source the "detector representation" of $S(x, y; \lambda)$ corresponds to the "super flat" S(x, y) defined above.

5.7.2 Wavelength calibration

At the wavelength calibration stage, the information of the pixel to wavelength associations is not yet available (that is rather the result or purpose of the wavelength calibration) the flat fielding has to be performed here using a IFS flat field frame which has not been divided by the detector flat, but is a measure of both detector and IFU flat. That is, DF and IF are not known separately, but rather together. The quantity $DF(x,y,\lambda) \times IF(x,y,\Delta x,\Delta y,\lambda)$ integrated over the associated pixel wavelengths is just the super flat field defined in 5.3.So, as a first step, after dark subtraction, the raw wavelength calibration frames are divided by the super flat field (as measured directly in the sph ifs instrument flat recipe).

The flat fielded signal, $S_{\Delta x,\Delta y}(x,y;\lambda)$ is then analysed to detect the spectral lines of the wavelength calibration amp. The calibration lamp produces very sharp, monochromatic lines. The line profile as observed on the detector are a convolution of the intrinsicline profile, negligible for the calibration lamp lines used, and the instrumental profile (spectrograph resolution). Therefore, the expected line width for these new calibration hardware willbe entirely given by the spectrograph resolution (about 2 pixels). Since the calibration lines are sharp, there is a possibility of some additional faint lines due to fringing, and so the positions on the spectra lineshave to be determined by pre-selecting the regions close to the expected positions of the lines to avoid the fitting to be performed on some of these fringes (present as local maxima). Alternatively, the data extracted from the spectra region is first passedthrough a low pass filter to smooth out fringes before fitting is performed-before de-convolving again to assure that the measured FWHM is not affected. The line fringing is not expected to be an important effect for IFS, wherespectra resolution is low, but for IRDIS MRS spectroscopy line fringinghas to be taken into account. Only the first, simplest method is currently implemented. The peak position for each line is determined by calculating the weightedmean position for a window of a few pixels size around the expected lineposition. The expected line position is taken from an input model of the spectrapositions and the dispersion. Since

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 171/220

this input can also be another wavelength calibration product, thewavelength calibration can in principle be performed iteratively.

Once the line positions have been identified, a polynomial of degree P > 0 is used to fit the curve of known line wavelengths to measured pixel coordinates. This fit is then used to fill all pixels not covered by lines with wavelengthinformation. If P > 1 the second derivative is used to estimate the dispersion.

5.8 Further spectral and flux calibrations

The IFS uses IFU capabilities to create a wavelength data cube as the mainscience product of every observation. This wavelength data cube needs to be, as much as possible, free of instrumental effects and measure as accurately as feasible the true spectrum of the source. However, the observed spectrum is, just like the detector image, affected by several unwanted effects: the atmosphere as well as telescope subsystemintroduce wavelength dependent effects. The observed spectrum is given by:

$$F_{obs}(\lambda; z, r, \theta) = F_{real}(\lambda) \times A_{atm}(\lambda; z) \times A_{corono}(\lambda; r, \theta) \times A_{tel}(\lambda; r, \theta) + T_{atm}(\lambda; z), \tag{5.7}$$

where $A_{atm}(\lambda;z), A_{chorono}(\lambda;r,\theta)$ and $A_{tel}(\lambda;r,\theta)$ are the attenuation effects of the atmosphere, the coronagraph and the telescope, respectively, $T_{atm}(\lambda;z)$ is the atmospheric transmission at wavelength λ and $F_{real}(\lambda)$ is the true scientific signal to detect, which needs to be reconstructed in the calibration procedure. In order to be able to do this, without the need to obtain calibration frames for every science exposure, it is necessary to model the various instrumental and atmospheric effects individually and measure the relative contributions and model parameters at regular intervals. To this end, the various effects can be disentangles making use of the different dependencies: the atmospheric effects depend on airmass, z but are independent of source location on the detector, whereas telescope and coronagraph affect the signal dependent on the source position within the frame but are independent of air mass. The various components are modeled and calibrated as follows.

5.8.1 Atmospheric absorption

In order to remove the atmospheric dependence, it is necessary to use aspectral model of a known observed source. To avoid a strong dependence of the data reduction pipeline on model dependent quantities, the recipes for atmospheric calibration currently produce simplereduced science frames. These have to be processed further by e.g. dividing by the known star spectra to obtain the atmospheric contribution.

5.8.2 Coronagraph effects

In general, the contribution of the coronagraph is not removed. Frames are processed without division by the coronagraph attenuation to reduce the impact that the incorrect removal of its effect may have onthe data quality.

In the rare cases where a removal of the coronagraph effect is explicitly required, exposures can be taken with and without coronagraph and the ratio of the resulting spectra gives directly the

¹Alternatively, a dispersion model which gives the dispersion as a function of wavelength, $D(\lambda)$ is used to create a "guess" pattern of line positions for each lenslet, and this pattern is matched to the observed line pattern (allowing for positional shifts). The "goodness" of fit of the pattern is calculated for each lenslet and can be used to monitor the dispersion stability of the lenslets. The dispersion $D(\lambda)$ model can also be created as an output of the wavelength calibration when the polynomial fit is used to obtain line positions; the wavelength calibration can in fact be regarded as a measurement of the dispersion for each lenslet.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 172/220

coronagraphic effect (except for an unknown normalization constant). However, the fact that measurements are necessary at different points in the field makes this rather problematic if no good model of the coronagraphic effect with few parameters is found. It should be possible to determine a functional model, $A_{corono}(\lambda,r,\theta;\alpha_0,\alpha_1,...,\alpha_N)$ with N parameters $\alpha_0,...,\alpha_N,$ and N being a small number. The parameters of the model and verification will have to be determined in the first weeks after or during commissioning.

5.8.3 Instrumental background and sky background

In 5.1no additive effects are included except those arising from the detector. However, there are signal contributions from both the sky and the instrumentitself which need to be removed in order to obtain the true science signal. Since these are additive effects, they need to be subtracted out afterthe reverse propagation equation above, 5.2has been applied. The total signal is

$$S_{tot}(x, y; \lambda) = S_{sky}(x, y; \lambda) + S_{ins}(x, y; \lambda) + S_{sci}(x, y; \lambda),$$

where S_{sky} is the sky background, S_{ins} is the instrument background and S_{sci} is the actual science signal. Note that these signals are additive – and so the calibration/removal of the sky and instrument background follows a similar procedure to the dark calibration, in the sense that they are subtracted from the input frames. Also note that all contributions have a wavelength dependence.

For IFS the contributions of the sky and instrument background are expected to be small and unimportant for the main science objective: the detection imaging of planets. It is only in special cases, for example when extended source are observed, that the sky and instrument background may significantly affect the sciencegoal of the observations. Therefore, even though recipes are included in the pipeline to calibrate these effects, their applicability will be limited.

5.8.4 Flux normalization calibration

Since the above calibrations are all performed using ratios, it is not possible to determine in this way the absolute flux. In order to do this, one needs to observe a known source and compare total received flux (i.e. detector counts) with the known flux of the source. This requires a separate calibration procedure: sph_ifs_std_phot and sph_ird_ins_throughput. For more details, see the description of the recipes.

5.9 Time dependency impact of systems

In the above treatment of the signal propagation for the individual calibrations, we have not discussed the effect of time variation in the various detector, instrument and telescope systems. None of these systems are perfectly stable in time, meaning that it is necessary to repeat calibration procedures at time intervals which are less than the stability time-scale for the required accuracy. For example, the detector flat field is stable to within 0.1% only for about one hour. This means that the recipes that need to correct for effects that involve the $DF(x,y,\lambda)$ term need to use calibration measurements of this quantity that are maximally one hour old. An alternative in such cases it to use monitoring measurements to construct a model of the time behaviour of the relevant subsystems. In the following table, we list approximate dependencies of the calibration terms:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58

Date: 2025-06-11 Page: 173/220

Term	Variable dependence	Time-scale	Variation
DC(x,y)	x, y	1 day	1%
B(x,y)	x, y	1 day	1%
$DF(x, y, \lambda)$	x, y	30 mins	0.1%
$DF(x, y, \lambda)$	λ	1 week	0.1%
$IF(x, y, \lambda)$	x, y	1 day	0.1%
$IF(x, y, \lambda)$	λ	1 month	0.1%
$TF(x, y, \lambda)$	x, y	1 week	1%
$TF(x, y, \lambda)$	λ	1 month	1%

It is the responsibility of the observer to make sure that the frames used for the calibrations have the required "freshness"—the pipelines will make no checks for that. Also note that some calibration procedures measure quantities that are combinations of terms with different time variability. In these cases, the acceptable time-scale is given by the smallest acceptable time-scale of the subsystems involved. For example, the instrument flat field procedure measures the term $DF(x,y,\lambda) \times IF(x,y,\lambda)$ which has an acceptable time scale for stability of about 30 mins - 1 hour. In some cases, it is also possible to model the time variability in such a way that only part of the procedure has to be performed in frequent intervals. For example, to perform accurate removal of the detector flat field inwavelength calibration it is in principle necessary to have detector flat-frames for all 4 calibration lamps that are all newer than 1 hour. However, modeling the behaviour of the detector flat field as

$$DF(x, y, \lambda) = DF(x, y) \times f(\lambda),$$

and noting that the detector response is very stable in terms of the wavelengthdependence, $f(\lambda)$ is almost constant over time, it is possible to only perform measurements of D(x, y) frequently, which requires taking calibration data with only a single lamp. This is the approach taken in SPHERE.

5.10 Clean Mean Algorithm: Basic Frame Combination with outlier rejection

Please note the spatial derivative pixel rejection described below has not been implemented in SPHERE.

The clean mean algorithm is used to average frames taking into account the possibility of bad pixels and outliers in individual frames. The quality of the detector linearity will therefore be an important contributor to the quality of the data reduction process in SPHERE. The goal is to achieve an optimal mean frame that is not affected by individual bad or outlying pixels at the same time as keeping the maximum amount of information.

We use iterative clean mean with sigma computation (following that described in ESO's SINFONI Pipeline User Manual) as our baseline frame combination method. For this process, the user sets minimum and maximum allowable intensity values. For a stack of frames, values inside this range are then used to determine an intensity mean and standard deviation, for each pixel position. Pixels with values differing from the mean by $k\ast std$ are removed. This process is re-iterated n times to generate a final mean-combined image.

We wrote an alternative frame combination script with the aim of achieving superior outlier rejection, compared to the clean mean method. This alternative procedure (presented in [RD2]) uses an iterative median/mean combination outlier rejection strategy that takes advantage of the spatial derivative of an image to better deal with variations from a changing PSF shape or small (sub-pixel) pointing errors. This is particularly important in regions where the PSF slope is steepest: there, a small change in pointing or PSF shape could lead to pixel values being wrongly interpreted as outlier pixels. The spatial derivative method should be effective at dealing with such phenomena, as demonstrated in data reduction for Spitzer IRAC (see [RD3]) and HST ([RD4]).

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 174/220

The code operates by first conducting a biased-median-combination of inputframes to create a best estimate image. "Biased median" refers to taking the value bpositions below the median value, to deal with non-symmetrical noise sourceslike cosmic ray effects. From this best estimate image, BEI, a spatial derivative array, SDA, may be calculated using the following equation.

$$SDA(x,y) = maxabs(BEI(x,y))[BEI(x-1,y),BEI(x+1,y),BEI(x,y+1),BEI(x,y-1)])$$
 (5.8)

Going back to the original input frames, we remove any pixel that differs in value from the corresponding best estimate image pixel by more than ktimes the corresponding pixel value in the SDA. In other words, we reject original input frame pixels that meet the following condition.

$$|original - frame(x, y) \in BEI(x, y)| > k \times SDA(x, y)$$
 (5.9)

The now-corrected input images are then mean-combined to generate the finalimage.

5.11 Detector pixel linearity

This algorithm is used for example in the sph_ifs_master_detector_flat recipeto determine the detector linearity for each pixel.

The linearity measurement is used in all recipes where the detector response is assumed to be linear as part of the algorithm. This is the case for all recipes that divide out the detector flat field for example, since the exact detector response is a function of input signal, and extrapolation to the actual input signal from the available detector flat calibration frames is needed (the value $DF(x,y,\lambda)$ in the equation 5.1 is just this linear detector coefficient).

Recipes that need to correct for the detector flat field actually use the detector pixel linearity for the flat fielding, since this gives the corrections a function of detector mean, rather than exposure time. The detector flat to correct for is a function of signal rather than integration time.

As part of this algorithm pixels are identified that do not conform with linearity requirements. Such pixels can also be regarded as "bad pixels" in the sense that their behaviour does not follow the expected behaviour—depending on the required accuracy such pixels may need to be excluded from a frame combination procedure. The identification of bad pixels using this method is possible both for dynamic and static bad pixel identification—but its main use is to identify static bad pixels. The algorithm itself only calculates the reduced χ -square of linear fits to each pixels response and the linear coefficients. Recipes can then use this information to flag certain pixels as bad.

This method to identify bad pixels can also be used to check that the dynamic bad pixel identification works as required and that the dynamic bad pixelidentification routine are not affecting further data calibration and reductions adversely.

To determine the detector pixel linearity for monitoring is responsibilitypart of the sph_ifs_gain recipe, where the response of every pixel to different signal levels is measured and a fit performed.

5.12 Bad Pixel Identification

Bad pixel identification in SPHERE happens on several levels and in severalways. First, there is a distinction between dynamic and static bad pixels. Static bad pixels are due to a property of the detector and are, as thename implies, unlikely to change with time. It may happen that a pixel changes its status from "good" to "bad" in terms of static bad pixel detection (i.e. the pixel breaks), but the converse should in general not occur. Dynamic bad pixels however vary from exposure to exposure. Identifying these is therefore responsibility for all algorithms that combine a set of raw frames into a smaller set of output frames, e.g. the CLEAN MEAN algorithm described in 5.10.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 175/220

5.12.1 Static Bad Pixel Identification

The identification of static bad (dead or hot) pixels in the data reductionoccurs usually during the master dark calibration recipe. When the master dark frames are created, a static bad pixel map is created the following way:

- 1. The master dark calibration frames are created from the input frames. As described in section 7, a master dark is created for every exposuretime and readout.
- 2. The individual frames are combined using the clean mean method, effectively removing temporary bad pixels that appear in only a few of the frames.
- 3. A threshold clipping is applied to the combined frames
- 4. A smoothed version is subtracted (this is an optional step)
- 5. A two-pass sigma clipping is applied

This routine ensures that static bad pixels are truly static and are not random chance events. However, note that a reliable identification of truly static pixels requires that the sigma threshold in identifying the bad pixels in each master calibration frame is chosen adequately and that there is a reasonable (i.e.more than about 3) number of exposure time set-ups in the input frames.

A second procedure to detect static bad pixels uses the detector linearitybehaviour to determine bad pixels. During the sph_ifs_detector_flat fielding recipe, a detector linearitymap is created (see 5.11). This map gives, for every pixel, a measure of the linearity (goodness offit for a linear fit) and the linearity coefficient. This map can then be used to flag pixels as bad. Many recipes allow a parameter to control the threshold on the linearity to accept/reject pixels. The detector flat recipe itself creates a static bad pixel map in this way, which is the standard bad pixel map input for other recipes.

The static (or "hot") bad pixel map identified using the first method, in the sph_ifs_master_darkrecipe, is used primarily for monitoring purposes and to validate the staticbad pixels identified in the sph_ifs_master_detector_flat field recipe. For that purpose the detector flat field recipe outputs a quality controlparameter that measures the number of pixels that have been identified in one static bad pixel map, but not the other. A large number here usually means that the detector linearity performancehas degraded.

5.12.2 Dynamic Bad Pixel Identification

Apart from static bad pixels due to faults in the detector, there are alsodynamic bad pixels that are created by transient effects: most notablyby cosmic rays. These are identified whenever raw frames are combined. Each frame combination routine, like the clean mean algorithm above, needsto reject pixels that are deemed as bad – in the case of the clean meanalgorithm due to their value away from the mean value. Since bad pixels due to cosmic rays can affect neighboring pixels as wellas the same pixel at a subsequent readout, all pixels around a bad pixel (in a cross shape) should also be flagged as bad as well in the subsequent frame. This happens, for pixels that are sufficiently outlying, automatically in the clean mean algorithm.

5.12.3 Bad pixel treatment in the IRDIS and ZIMPOL science recipes

The science reduction recipes for IRDIS and ZIMPOL use the bad pixel maps from the dark and the flat field recipes to set the bad pixels on the resulting reduced science images. The bad

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 176/220

pixels set in the science frames is always the union of all staticbad pixel maps. Both IRDIS and ZIMPOL use geometric transformations as part of the usual science data reduction process (e.g. for differential imaging or to process dithered frames) and the bad pixel maps are transformed along with the image. The algorithm for transforming the bad pixel maps is purely geometric inany case even when the image data is transformed using an FFT. Due to serious artefacts that would arise if an FFT is performed on datacontaining many discontinuities arising from bad pixels, the science recipes interpolate the bad pixels before any transformation on the image data. The (also transformed) bad pixel map however is maintained and used to calculate a final bad pixel map on the fully reduced and combined science image that then shows as bad all pixels that had no valid input pixel information.

5.13 Field Center

For all SPHERE instruments accurate determination of the field center isimportant. The required accuracy currently is 3mas with a goal of 1mas. This is true in particular for all pupil stabilized (or fixed de-rotator) modes. Here frame combination as described in 3.14 requires de-rotation of rawframes and for this the rotation center needs to be determined accurately. The situation as given from the hardware is as follows:

- the DTTS loop and reference slopes calibration ensures that:
 - this center of rotation is also the photo center and
 - this is also the location of coronagraph (all of this with satisfactoryaccuracy <0.5 mas)
- the DTTS calibration (CPI-TEC-01) outputs the position on the IRDIS detector of the coronagraph (for its internal use)

Currently there are several different field center calibration strategies considered:

- 1. Calibration within science data reduction recipes: here one uses the scienceraw frames themselves and the fact that the coronagraph center can be easilydetermined by determining the center of the region masked by the coronagraph. The AO (DTTS loop) then ensures that this coronagraph center is also therotation center. For frames taken without coronagraph the star center itself, which is easilydetermined by finding the peak and Gaussian fitting.
- 2. Calibration of the center in a dedicated recipe but using the input rawscience observation frames. For IRDIS the star center calibration which uses 4 secondary diffraction peaks to extrapolate the center of the star and hence the rotation center.
- 3. Dedicated calibration recipe using an artificial source. An artificial illumination source is used to perform a dedicated calibration which determines the center of the coronagraph for all possible instrumentset-ups. This would be a daytime calibration with a as yet to be determined frequency. A dedicated recipe would reduce these calibration images and return a reference field center to use for frame combination in science data reduction recipes.

Currently, option 2 has been implemented for IRDIS in the sph_ird_star_centerrecipe. Which of these will be implemented for IFS is still to be decided.

5.14 Frame combination: de-shifting and de-rotating

Frame combination is one of the most crucial steps in the SPHERE data reductions ince accurate frame combination including de-shifting and de-rotational lows use of ADI, SDI and other more advanced planet finding algorithms.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 177/220

In SPHERE the frame combination including de-rotation, scaling (for SDI) and de-shifting is intended to be an integral part of the pipeline on the other hand and to be flexible and modular on the other. This is realised by allowing the choice of frame-combination to be given as an input parameter to recipes, along with all relevant parameters needed for the frame combination algorithm. Currently only a simple ADI and SDI is implemented.

For IRDIS the algorithm of choice to de-shift, de-rotate and de-scale is the FFT. The exact FFT implementation is a separate module and de-coupled from the actual frame-combination code so it can be replaced with different implementation easily. Currently the FFT provided by FFTW is used. The GSL fft routines are also available using a switch (recompilation is necessary).

The FFT rotation routine is augmented by a filter to remove high frequencynoise. This filter is a simple top-hat filter which removes all frequencies that have a k-value in the Fourier domain that is above a percentage F of them aximum k-value.

For IFS, the algorithm to de-rotate the individual monochromatic images uses the hexagonal lenslet array geometry and the algorithm GIMROS.GIMROS calculates overlaps between polygons to interpolate the lensletimage onto a rotated grid of hexagons.

5.14.1 GIMROS - Generic IMage ROtation and Scaling

The GIMROS algorithm is specifically created to interpolate the image from a hexagonal grid onto a translated and/or rotated second hexagonal grid.

5.14.1.1 The concept behind GIMROS

The "G" in GIMROS means Generic and indicates that the concept of rotatingand scaling image data is somewhat generalized in this algorithm. Not as strictly tied to astronomical purposes like in the IPAC Montagepackage, where every pixel is projected onto the sky before being mappedonto a new pixel grid, but more general in the sense of allowing more pixelshapes. Of particular interest in SPHERE's context are of course the hexagonalpixels of IFS, but in principle GIMROS allows for all convex polygons asimage base elements. In fact, an image representation suitable for GIMROS must be more complexthan simply a matrix full of values plus a header that describes how theindices's of matrix elements are related to image co-ordinates.

5.14.1.2 Transforming an image with GIMROS

The primary transformation technique applied by GIMROS will be to map theinput fluxes collected on the input pixel grid to a given output pixelgrid. The calculation of the coordinates of the output pixel grid is determined by the transformation and usually not performed by GIMROS itself. A few helper routines may be devised that perform simple special transforms such as arbitrary rotation about an arbitrary centre, arbitrary shiftsin arbitrary directions, and image scaling.

The flux value of any output pixel F(i) will be calculated as the sum overall overlapping input pixels flux values G(j) weighted with the overlapparea:

$$F(i) = \frac{\sum G(j)a_{ij}}{\sum a_{ij}}$$

It is obvious that this technique is flux conserving as long as both images are completely and continuously covered with non-overlapping pixels. Gaps between pixels, particularly in the output image, may of course lead to losses of flux.

The overall algorithm of GIMROS then looks as follows:

```
for all output pixels: area weight = 0
```

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 178/220

```
flux = 0
find all potentially overlapping input pixels
for current_input_pixel
in potentially_overlapping_input_pixels:
area = overlap_area(current_input_pixel, current_output_pixel)*
current_input_pixel.weight area_weight += area flux +=
current_input_pixel.flux * area
if flux != 0:
flux /= area weight
```

The introduction of the current_input_pixel.weight allows for handling badpixel maps on the input side

The finding of the potentially overlapping input pixels can be done in the following way:

- 1. calculate all centre points of all (transformed) input and output polygons
- 2. find the longest distance between centres and any edge point throughout the input ar
- 3. sort the pixel polygons by the distance of their centre point to the centrepoint of
- 4. the potentially overlapping pixels are the ones where the distance is below 2*dmax

The calculation of the overlap are is done by clipping the (transformed)input polygon to the output polygon and calculating the area of the resulting, clipped polygon. For details of this procedure, see http://www.mpia.de/SPHERE/WIKI/pmwiki.php?n=DRH.FrameCombination.

5.15 Creating wavelength cubes for IFS

One of the last reduction steps in producing calibrated science frames for IFS is to construct a wavelength data cube, $S(\alpha,\beta,\lambda)$. As described before, this is achieved using pixel-to-lenslet association tables. The interpretation of the resulting cubic structure is, however, not straightforward unless some additional geometric transformations are used. The reason is that the lenslet array has a hexagonal rather than rectangular structure. This means that every spatial x,y position in the wavelength cube has a non-trivial associated sky position α,β . How this geometric transformation is performed depends on the level of science reduction. For the basic reduction there is two possible outputs: a result on a hexagonal grid as a FITS table, representing a hexagonal "cube" and a result on a (square) pixel cube. In each case, the way that the interpolation onto the output grid is performed depends on the observing mode: field or pupil-stabilized. We describe the general algorithm for creation of wavelength cube below.

The starting point for cube creation is in any case a series of detectorimages. Spectra have been identified using the sph_ifs_spectra_locations and sph_ifs_wave_calib routines, which have created a master pixel description table, describing pixel wavelength associations for the standard zero-point dithering position. For each dithering position used in the observations to combine, a newPDT has to be constructed. This is done purely in a software manner – calculating a new PDT for theoffset position from the master PDT using the sph_pixel_description_table_new_shift function. These PDTs can then be used to extract a spectrum for every raw input frame—thus providing dither independent information. The extracted spectra are saved in a structure called a "lenslet description table" (LDT) which describes the data in terms of the the lenslet "view" of IFS. The LDT is strongly linked to the IFS instrument model, described in 4.2.1. Extracting the spectra and moving to the lenslet view removes any dithering dependence and spectra can now be combined. This is done on a spectrum by spectrum basis. Once a final combined set of spectra has been crated (one spectrum foreach lenslet) the result is saved as a wavelength cube. For this, the hexagonal structure is interpolated onto a hexagonal grid. We have currently implemented a method based on GIMROS to project hexagonsonto quadratic pixels.

Issue: 1 Version 58
Date: 2025-06-11 Page: 179/220

5.16 Distortion map

The distortion map needs to be measured for IFS and IRDIS.For ZIMPOL no distortion map measurement is currently foreseen, but it may be added at a later stage. For IRDIS the distortion map measures the distortion of the actual detector, $\Delta(x,y) = [\Delta_x(x,y), \Delta_y(x,y)]$, defined by

$$S(x,y) = S'(x + \Delta_x(x,y), y + \Delta_y(x,y))$$
(5.10)

where S(x,y) and S'(x,y) represent the distortion corrected and uncorrected signal respectively. For IFS the distortion map of the lenslet array itself is the relevant quantity, which is defined in an analogous way.

In both cases, the distortion is measured using a grid of artificial sources with known positions. The grid positions is used as an input to the distortion map recipe which detects the actual observed sources and measures their displacement with respect to the expected positions to obtain a vector map. The x and y component of this vector map is fit using a 2D polynomial, giving a smooth representation of the distortion map.

5.17 Astrometry and plate scale solution

The field of view for all SPHERE instruments is very small and astrometryfor SPHERE is a two parameter problem: the rotation angle relative to the north direction and the pixel scale. The field center itself is determined in a separate recipe.

To allow the determination of the two parameters, a binary system needs to be observed. The relevant recipes reduced the raw observation frames and automatically detect the central star and the companion. Together with the user input parameters of angle and separation the angleto north and plate scale are derived.

5.18 ZIMPOL measurements

5.18.1 Definitions of terms used for ZIMPOL measurements

In this document and in the SPHERE ZIMPOL calibration plan (RD1), several expressions are used for describing specific parts of a ZIMPOL measurement. The different expressions aim to better distinguish between the entities they describe and are chosen according to ESO definitions described in AD1.

Exposure: In general, an *exposure* is the entity of one or more (NDIT) integrations (*frames*), followed by the readout and storage of the NDIT *frames*.

- For ZIMPOL polarimetric modes (P1, P2, P3), an exposure is always the entity of two or multiples of two (2·NDIT) frames (due to the double-phase mode) each followed by detector readout and storage of the 2·NDIT frames. A ZIMPOL measurement of one Stokes parameter requires a minimum (NDIT=1) of one exposure, i.e. one exposure contains two frames or four sub-frames.
- For ZIMPOL imaging mode (I1), an exposure means the entity of one or more(NDIT) integrations (frames), each followed by detector readout and storage of the NDIT frames.

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 180/220

Frame: A frame is a single integration and readout of the data acquired during DIT seconds. Two frames in sequence in double-phase mode form the minimum of one ZIMPOL exposure. Each frame has a 'number' $k = 1 \dots 2 \cdot \text{NDIT}$.

Sub-frame: In general, a sub-frame is a part of a frame. For ZIMPOL, each frame consists of exactly two sub-frames independent of observing mode: The image data stored in all odd-numbered, exposed software pixel rows (sub-framei^A), and that stored in all even-numbered pixel rows covered by the opaquestripe mask (sub-framei^B). In the polarimetric modes P1, P2, P3, the demodulation fills the two sub-frames with the two complementary polarization images. The spatial field information in both sub-frames is the same, since they have been recorded through the same microlenses and exposed pixels. In imaging mode I1, where no demodulation takes place, the intensity image stored only in the sub-framei^A while the other sub-framei^B remains empty.

5.18.2 Description of a ZIMPOL measurement in double-phase mode

To better understand and distinguish the different meanings of exposure, frame and sub-frame, a short explanation is given which is valid for all ZIMPOL double-phasemode measurements. Each frame (number $k=1...2\cdot \text{NDIT}$) contains two sub-frames, i_k^A and i_k^B . Polarization modulation of the incoming light in combination with the demodulation performed on the CCD sensor during the integration time ensure that these two sub-frames represent an intensity image of two opposite Stokes polarization components (e.g. Q_+ stored in i_k^A , Q_- in i_k^B). In double-phase mode, the demodulation phase is shifted by half a cycle between each consecutive pair of frames, effectively exchanging the assignments (Q_+ stored in i_{k+1}^B , Q_- in i_{k+1}^A). In Figure 5.2a graphical explanation is given.

When a cycle of NDIT frames is taken, the half-wave plate HWP2 is rotated by 45° ("HWP2 flip"), and the cycle of NDIT frames is repeated for the second HWP2 position. When the observations for both HWP2 positions are finished, an optional dithering is performed over NDITHER positions.

5.18.3 ZIMPOL CCD

The two chosen ZIMPOL CCDs are e2v 44-82 bi, in frame transfer mode (oneCCD for each of the two cameras). One CCD has $2k\times 4k$ pixels (hardware pixels of $15\times 15~\mu m$ size). The half of the CCD ($2k\times 2k$) is covered by an opaque mask and is used as buffer storage only, the other half ($2k\times 2k$) is exposed to light. The exposed part of the CCD is furthermore equipped with an opaque stripe mask which alternately covers two rows of the CCD and leaves the next two rows open (e.g.row 1 and 2 are covered, 3 and 4 are open, 5 and 6 covered, 7 and 8 open, etc.). An on-chip (TBC) 2×2 binning will reduce this to $1k\times 1k$ software pixels ($30\times 30~\mu m$ size). Thus, from each camera $1k\times 1k$ pixels are effectively read out.

The f/ number at the detector is f/221, leading to an image scale of $\approx 0.117\,\mathrm{mas}/\mu\mathrm{m}$ a pixel scale of $3.5\,\mathrm{mas/pixel}$ (for $1\mathrm{k}\times1\mathrm{k}$ pixels).

The image scale in the sub-frames $(1k\times0.5k)$ is doubled in one field direction. To make the image scale symmetric in both field directions, the imageswill be binned again during the data reduction to $0.5k\times0.5k$ final pixels of size $60\times60\,\mu\mathrm{m}$ corresponding to an image scale of $\approx 0.233\,\mathrm{mas}/\mu\mathrm{m}$ or a pixel scale of $7\,\mathrm{mas}/\mathrm{pixel}$. This corresponds to about half a resolution element at $600\,\mathrm{nm}$, which is $\lambda/D\approx15.5\,\mathrm{mas}$ (factor 1.1 oversampling compared to Nyquist criterion at $600\,\mathrm{nm}$).

The total field of view at the ZIMPOL focal plane is about 8" diameter, whereas the entire detector covers only about 3.5×3.5 ".

An extract of one ZIMPOL CCD can be seen in Figure 5.18.3. There, the boxes with the smallest sizes correspond to the 15 μ m sized hardware pixels. The always present on-chip (TBC) 2×2 binning

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 181/220

ZIMPOL - exposure

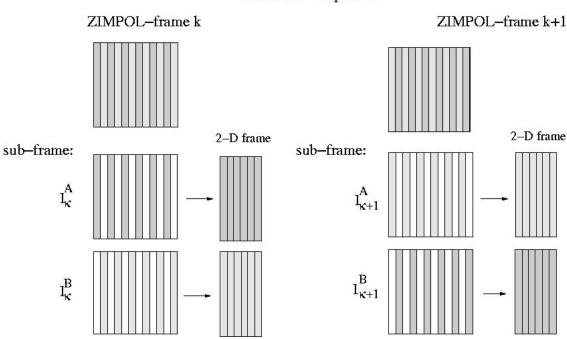

Figure 5.2: Schema of one single ZIMPOL exposure for the example of NDIT=1, leading to the output of two consecutive frames from each CCD. The left side is the kth ZIMPOL frame recorded at phase one of the double-phase mode, whereas the right side (frame k+1) has been recorded in the second phase. Each frame contains two interlaced sub-frames, storing two complementary polarization component images. Since the frame is square, extracting the two sub-frames yields two images with a 1:2 aspect ratio; a circle will be imaged as an ellipse). Dark grey means more intensity than light grey; white means that these columns contain no scientific data (but only noise).

leads to the software pixels of $30\times30~\mu\mathrm{m}$ size which are read out. Later in the data reduction binning is applied anew, shown here with the largest filled box. A circle with the diameter of diffraction limited resolution is over-plotted to visualize the relations.

5.18.4 Dithering

Dithering is foreseen for all ZIMPOL observations. It will be implemented by keeping the telescope pointed at a fixed position the sky and producing a series of movements of the tilt- and tip/tilt-mirrors in front of the ZIMPOL cameras providing a series of x, y-shifts of the field of view by a certain number of pixels.

The proposed idea is to enter a number of dithering positions (NDITHER) and the individual x, y offsets $(\Delta x_i, \Delta y_i)$ in the P2PP. The input NDITHER and the number of $(\Delta x, \Delta y)$ -pairs are compared, and an error is signalized if they do not match. The offsets $(\Delta x_i, \Delta y_i)$ can be given in arcseconds or in pixel numbers (units to be selected from menu bar). The numbers are calculated by the INS and the commands are given to the motors of the tilt- and tip/tilt mirrors. It shall also be possible to select predefined dithering positions, e.g. 9 (or 25) positions with the pointing at the center and the remaining 8(or 24) positions aligned in a grid around the pointing position with offsets of e.g. 2 pixels. For each NDITHER position both HWP2 positions with NDIT frames each can be taken at the fixed position of FOV (telescope and tilt- and tip/tiltmirrors). The observation sequence is according to the "Observations modes and sequences" (RD4) the following:

        take 1 frame with the second mode of the double-phase mode
    end for
end for
```

5.18.5 Two-phase mode

In polarimetric detector modes, two more calibrations must be applied to the data after dark subtraction and intensity flat-fielding. As described in Section 5.18.2, each ZIMPOL frame kconsists of two interlaced sub-frames $i^{\rm A}(k)$, $i^{\rm B}(k)$ that each store one polarization component, e.g. Q_+ , Q_- . From one frame to the next, the assignment of polarization components to sub-frames is reversed by switching the phase of the demodulation cycle from 0 to π , whereas the detector's fixed pattern noise (FPN) remains unchanged. This property is exploited to remove the fixed pattern noise:

REF: VLT-TRE-SPH-14690-660/1/0

Issue: 1 Version 58
Date: 2025-06-11 Page: 183/220

$$Q^{(0)} = i_k^{A} - i_k^{B} = \frac{1}{2} \left(\left(+Q + FPN^{A} \right) - \left(-Q + FPN^{B} \right) \right), \tag{5.11}$$

$$Q^{(\pi)} = i_{k+1}^{A} - i_{k+1}^{B} = \frac{1}{2} \left(\left(-Q + FPN^{A} \right) - \left(+Q + FPN^{B} \right) \right), \tag{5.12}$$

$$Q = \frac{1}{2} \left(Q^{(0)} - Q^{(\pi)} \right). \tag{5.13}$$

The fixed pattern noise of a given pixel has been assumed to be constanthere. In reality, it can depend on the flux of the pixel to some degree. If the pixel flux is different between the two polarization components, i.e. if $Q \neq 0$, some residual fixed pattern noise will survive this process. Therefore, it is imperative to keep the overall background polarization of the science image as low as possible. The ZIMPOL instrument uses a rotatable and tiltable glass plate to compensate the background polarization in real-time for this purpose.

5.19 Specific ZIMPOL detector calibration

We distinguish between two quite separate kinds of calibration: The detectorcalibration, which attempts to remove all detector imperfections from theread-out photocharge images and reconstruct the actual intensity distributionincident on the detectors (and is therefore locked to the grid of the detectorpixels); and the Stokes vector calibration, which attempts to reconstruct the scientific Stokes vector coming in from the sky on the basis of theintensity distributions that reach the detector after propagation through the instrument (and is therefore locked to the coordinate system of thesky image).

5.19.1 Modulation / demodulation efficiency

The modulation / demodulation polarimetric efficiency of the ZIMPOL instrument (the $Q \to Q$ element of its Mueller matrix) is dominated by effects of imperfect demodulation; therefore it is corrected pixel-wise as part of the detector calibration rather than as part of the Stokes vector calibration. The modulation / demodulation efficiency (MDE) is recorded under 100% polarized-flat illumination using two-phase mode. The Q/Iscience image is then divided by the resulting Q/Iefficiency frame to remove those effects.

Therefore, the clean polarization image can be obtained as follows:

$$(Q/I)_{\text{clean}} = \frac{(Q/I)}{(Q/I)_{\text{MDE}}}.$$

Chapter 6

Installation Procedure and Troubleshooting

6.1 Installing the Pipeline

ESO pipelines can be installed via several methods, depending on your OS, most of which facilitate easy installation, upgrade and removal. Please see the ESO Data Reduction Pipelines and Workflow Systems page https://www.eso.org/pipelines.

6.2 Tips, tricks, and troubleshooting

6.2.1 My recipe run terminats with thousands of error messages...

Don't panic! Try to go through the log file produced by esorex and findthe first ERROR signal.In many cases, this gives a hint what went wrong and what can be tried to correct the behaviour...

6.2.2 I still don't understand the error / it says that the 'actual error waslost'

Now panic! Better still, note that many parts of the pipeline are stilluntested and it's not unlikely you stumbled onto something that has neverbeen tried before. Try to make a small package of data and a commandline that can reproduce the error and contact us!

6.2.3 My distortion map or other peak-finding involving recipe doesn't producean output and gives errors.

Recipes involving peak finding usually offer a thresholdor sigmaparameter in the command line. Some also offer nsourcesto pre-determine the number of sources to be found. Try playing with these in conjunction to looking at the images, in particular the peak intensity in relation to the background level, which should bethresholdor sigmatimes apart. Note than in combination with a supplied as e.g. in sph_ird_star_center, the parameter value needed can be rather particular...so try also very large numbers here!
